

# PY32E407-B1 Series

32-bit ARM® Cortex® -M4F Microcontroller

## Reference Manual

Puya Semiconductor (Shanghai) Co., Ltd.

# Contents

|                                                     |           |
|-----------------------------------------------------|-----------|
| <b>1. LIST OF ABBREVIATIONS FOR REGISTERS .....</b> | <b>52</b> |
| <b>2. SYSTEM ARCHITECTURE BLOCK .....</b>           | <b>53</b> |
| <b>3. SYSTEM AND MEMORY ARCHITECTURE .....</b>      | <b>54</b> |
| 3.1 ARM® CORTEX® -M4F PROCESSOR INTRODUCTION .....  | 54        |
| 3.2 SYSTEM ARCHITECTURE .....                       | 54        |
| 3.2.1 <i>I_bus</i> .....                            | 55        |
| 3.2.2 <i>D_bus</i> .....                            | 55        |
| 3.2.3 <i>S_bus</i> .....                            | 55        |
| 3.2.4 <i>DMA1/DMA2 BUS</i> .....                    | 56        |
| 3.2.5 <i>ETH DMA BUS</i> .....                      | 56        |
| 3.2.6 <i>Bus matrix</i> .....                       | 56        |
| 3.2.7 <i>AHB/APB bus bridge</i> .....               | 56        |
| 3.3 MEMORY ORGANIZATION ARCHITECTURE .....          | 56        |
| 3.3.1 <i>Introduction</i> .....                     | 56        |
| 3.3.2 <i>Memory map</i> .....                       | 57        |
| 3.4 EMBEDDED SRAM .....                             | 60        |
| 3.4.1 <i>Parity check</i> .....                     | 61        |
| 3.4.2 <i>CCM SRAM Write Protection</i> .....        | 61        |
| 3.4.3 <i>CCM SRAM Read protection</i> .....         | 62        |
| 3.4.4 <i>CCM SRAM Erasure</i> .....                 | 62        |
| 3.5 EMBEDDED FLASH .....                            | 62        |
| 3.6 BIT SEGMENT .....                               | 62        |
| 3.7 START CONFIGURATION .....                       | 63        |
| 3.7.1 <i>System Storage Startup</i> .....           | 64        |
| 3.7.2 <i>Physical remap</i> .....                   | 64        |
| <b>4. EMBEDDED FLASH INTERFACE .....</b>            | <b>65</b> |
| 4.1 INTRODUCTION .....                              | 65        |
| 4.2 MAIN FEATURES .....                             | 65        |
| 4.3 FLASH MEMORY ORGANIZATION .....                 | 65        |
| 4.4 ERROR CODE CORRECTION (ECC) .....               | 66        |
| 4.5 READ ACCESS LATENCY .....                       | 66        |
| 4.6 ADAPTIVE REAL-TIME MEMORY ACCELERATOR .....     | 67        |
| 4.7 ERASURE AND PROGRAM OPERATIONS .....            | 67        |

|          |                                                          |    |
|----------|----------------------------------------------------------|----|
| 4.7.1    | <i>Unlocking the Flash memory</i> .....                  | 68 |
| 4.7.2    | <i>Flash memory erase</i> .....                          | 68 |
| 4.7.2.1  | Flash page erasure .....                                 | 68 |
| 4.7.2.2  | Flash sector erase .....                                 | 69 |
| 4.7.2.3  | Flash block erasure .....                                | 69 |
| 4.7.2.4  | Flash Bank Erasure .....                                 | 69 |
| 4.7.3    | <i>Flash memory programming</i> .....                    | 69 |
| 4.8      | FLASH OPTION BYTES .....                                 | 70 |
| 4.8.1    | <i>Flash option byte description</i> .....               | 70 |
| 4.8.1.1  | Option bytes for Flash user option 1 .....               | 71 |
| 4.8.1.2  | Option bytes for Flash user option 2 .....               | 72 |
| 4.8.1.3  | Option bytes for Flash WRP addresses .....               | 72 |
| 4.8.1.4  | Option bytes for Flash PCROP0SR address .....            | 73 |
| 4.8.1.5  | Option bytes for Flash PCROP0ER address .....            | 73 |
| 4.8.1.6  | Option bytes for Flash PCROP1SR address .....            | 73 |
| 4.8.1.7  | Option bytes for Flash PCROP1ER address .....            | 74 |
| 4.8.2    | <i>Flash Option Byte Write</i> .....                     | 74 |
| 4.8.2.1  | Modify option bytes .....                                | 74 |
| 4.8.2.2  | Load location bytes .....                                | 75 |
| 4.9      | FLASH USER OTP BYTE .....                                | 76 |
| 4.10     | FLASH PROTECTION .....                                   | 76 |
| 4.10.1   | <i>Flash Read Protection (RDP)</i> .....                 | 76 |
| 4.10.1.1 | Level 0: no protection .....                             | 77 |
| 4.10.1.2 | Level 1: Read protection .....                           | 77 |
| 4.10.2   | <i>Flash Write Protection (WRP)</i> .....                | 78 |
| 4.10.3   | <i>Proprietary Code Readout Protection (PCROP)</i> ..... | 78 |
| 4.10.4   | <i>Forced Boot from Main flash</i> .....                 | 78 |
| 4.11     | FLASH INTERRUPT .....                                    | 79 |
| 4.12     | TIMX REGISTERS .....                                     | 79 |
| 4.12.1   | <i>Flashaccesscontrol register (Flash_ACR)</i> .....     | 79 |
| 4.12.2   | <i>Flashkey register (Flash_KEYR)</i> .....              | 79 |
| 4.12.3   | <i>Flashoption key register (Flash_OPTKEYR)</i> .....    | 80 |
| 4.12.4   | <i>Flashstatus register (Flash_SR)</i> .....             | 80 |
| 4.12.5   | <i>FlashControl Register (Flash_CR)</i> .....            | 81 |
| 4.12.6   | <i>Flash ECC Register (FLASH_ECCR)</i> .....             | 82 |

|           |                                                                    |            |
|-----------|--------------------------------------------------------------------|------------|
| 4.12.7    | Flash Option1 Register (Flash_OPTR1) .....                         | 83         |
| 4.12.8    | Flash Option2 Register (Flash_OPTR2) .....                         | 83         |
| 4.12.9    | FlashWRP address register (FLASH_WRP) .....                        | 84         |
| 4.12.10   | FlashPCROP0 start address register (FLASH_PCROP0SR) .....          | 84         |
| 4.12.11   | FlashPCROP0 end address register (FLASH_PCROP0ER) .....            | 85         |
| 4.12.12   | FlashPCROP1 start address register (FLASH_PCROP1SR) .....          | 85         |
| 4.12.13   | Flash PCROP1 end address register (FLASH_PCROP1ER) .....           | 86         |
| <b>5.</b> | <b>POWER CONTROL (PWR) .....</b>                                   | <b>87</b>  |
| 5.1       | INTRODUCTION .....                                                 | 87         |
| 5.2       | POWER STRUCTURE .....                                              | 87         |
| 5.2.1     | System Main Power Supply .....                                     | 88         |
| 5.2.1.1   | Independent A/D converter power supply and reference voltage ..... | 88         |
| 5.2.1.2   | Backup battery domain .....                                        | 88         |
| 5.2.1.3   | VDDD voltage regulator .....                                       | 89         |
| 5.2.2     | Power Detection .....                                              | 89         |
| 5.2.2.1   | POR/PDR .....                                                      | 89         |
| 5.2.2.2   | PVD .....                                                          | 90         |
| 5.3       | SYSTEM LOW POWER MODE .....                                        | 90         |
| 5.3.1     | Normal Operating Mode .....                                        | 93         |
| 5.3.2     | Low power operating mode .....                                     | 93         |
| 5.3.3     | Low power mode entry and exit .....                                | 94         |
| 5.3.4     | Sleep Mode .....                                                   | 95         |
| 5.3.5     | Low power sleep mode .....                                         | 95         |
| 5.3.6     | Stop mode .....                                                    | 95         |
| 5.3.7     | Standby mode .....                                                 | 96         |
| 5.3.8     | Debugging of stop mode and standby mode .....                      | 97         |
| 5.3.9     | Automatic wake-up in low power mode (AWU) .....                    | 97         |
| 5.4       | TIMX REGISTERS .....                                               | 98         |
| 5.4.1     | Power Control Register 1 (PWR_CR1) (0x00) .....                    | 98         |
| 5.4.2     | Power Control Register 2 (PWR_CR2) (0x04) .....                    | 99         |
| 5.4.3     | Power Control Register 3 (PWR_CR3) (0x08) .....                    | 99         |
| 5.4.4     | Power Control Register 4 (PWR_CR4) (0x0C) .....                    | 100        |
| 5.4.5     | Power status register (PWR_SR) (0x10) .....                        | 101        |
| 5.4.6     | Power Status Clear Register (PWR_SCR) (0x14) .....                 | 102        |
| <b>6.</b> | <b>RESET AND CLOCK CONTROL (RCC) .....</b>                         | <b>103</b> |

|         |                                                                     |     |
|---------|---------------------------------------------------------------------|-----|
| 6.1     | INTRODUCTION .....                                                  | 103 |
| 6.1.1   | <i>Main Features</i> .....                                          | 103 |
| 6.2     | SYSTEM RESET .....                                                  | 103 |
| 6.2.1   | <i>NRST pin (external reset)</i> .....                              | 103 |
| 6.2.2   | <i>Software reset</i> .....                                         | 103 |
| 6.2.3   | <i>Low Power Management Reset</i> .....                             | 103 |
| 6.2.4   | <i>Option Byte Load Reset</i> .....                                 | 104 |
| 6.3     | POWER RESET .....                                                   | 104 |
| 6.4     | BACKUP DOMAIN RESET .....                                           | 104 |
| 6.5     | UNIFORM HANDLING OF RESETS OTHER THAN BACKUP DOMAIN RESETS .....    | 104 |
| 6.6     | CLOCK STRUCTURE .....                                               | 105 |
| 6.7     | CLOCK SOURCES .....                                                 | 105 |
| 6.7.1   | <i>HSE clock</i> .....                                              | 105 |
| 6.7.2   | <i>HSI16 clock</i> .....                                            | 106 |
| 6.7.3   | <i>HSI48 clock</i> .....                                            | 106 |
| 6.7.4   | <i>PLL clock</i> .....                                              | 106 |
| 6.7.5   | <i>LSE clock</i> .....                                              | 106 |
| 6.7.6   | <i>LSI clock</i> .....                                              | 106 |
| 6.7.7   | <i>HSI10M clock</i> .....                                           | 107 |
| 6.8     | CLOCK SECURITY SYSTEM (CSS) .....                                   | 107 |
| 6.9     | PERIPHERAL CLOCK ENABLE REGISTER .....                              | 107 |
| 6.10    | TIMX REGISTERS .....                                                | 107 |
| 6.10.1  | <i>Clock control register (RCC_CR)</i> .....                        | 107 |
| 6.10.2  | <i>Clock configuration register (RCC_CFGR)</i> .....                | 109 |
| 6.10.3  | <i>Clock Interrupt Register (RCC_CIR)</i> .....                     | 110 |
| 6.10.4  | <i>AHB1 peripheral reset register (RCC_AHB1RSTR)</i> .....          | 112 |
| 6.10.5  | <i>AHB2 peripheral reset register (RCC_AHB2RSTR)</i> .....          | 112 |
| 6.10.6  | <i>APB1 peripheral reset register 1 (RCC_APB1RSTR1)</i> .....       | 113 |
| 6.10.7  | <i>APB1 peripheral reset register 2 (RCC_APB1RSTR2)</i> .....       | 115 |
| 6.10.8  | <i>APB2 peripheral reset register (RCC_APB2RSTR)</i> .....          | 115 |
| 6.10.9  | <i>AHB1 peripheral clock enable register (RCC_AHB1ENR)</i> .....    | 116 |
| 6.10.10 | <i>AHB2 Peripheral Clock Enable Register (RCC_AHB2ENR)</i> .....    | 117 |
| 6.10.11 | <i>APB1 peripheral clock enable register 1 (RCC_APB1ENR1)</i> ..... | 118 |
| 6.10.12 | <i>APB1 peripheral clock enable register 2 (RCC_APB1ENR2)</i> ..... | 119 |
| 6.10.13 | <i>APB2 peripheral clock enable register (RCC_APB2ENR)</i> .....    | 120 |

|           |                                                                               |            |
|-----------|-------------------------------------------------------------------------------|------------|
| 6.10.14   | <i>Peripherals independent clock configuration register (RCC_CCIPR)</i> ..... | 121        |
| 6.10.15   | <i>RTC domain control register (RCC_BDCR)</i> .....                           | 122        |
| 6.10.16   | <i>RCC control/status register (RCC_CSR)</i> .....                            | 123        |
| 6.10.17   | <i>Clock configuration register 1 (RCC_CFGR1)</i> .....                       | 124        |
| 6.10.18   | <i>Clock configuration register 2 (RCC_CFGR2)</i> .....                       | 125        |

| <b>38.</b> | <b>UNIVERSAL ASYNCHRONOUS RECEIVERS/TRANSMITTER (UART)</b> ..... | <b>1003</b> |
| 38.1       | INTRODUCTION .....                                               | 1003        |
| 38.2       | MAIN FEATURES .....                                              | 1003        |
| 38.3       | UART FUNCTIONAL DESCRIPTION .....                                | 1003        |
| 38.3.1     | <i>UART (RS232) serial protocol</i> .....                        | 1003        |
| 38.3.2     | <i>9-bit data transfer</i> .....                                 | 1004        |
| 38.3.3     | <i>Baud rate</i> .....                                           | 1007        |
| 38.3.4     | <i>The UART receiver tolerates changes in the clock</i> .....    | 1008        |
| 38.3.5     | <i>Continuous Communication Using DMA</i> .....                  | 1009        |
| 38.3.6     | <i>Interrupts and events</i> .....                               | 1010        |

|          |                                                                           |             |
|----------|---------------------------------------------------------------------------|-------------|
| 38.4     | TIMX REGISTERS.....                                                       | 1010        |
| 38.4.1   | UART DR, Address = 0X00 (DR) .....                                        | 1010        |
| 38.4.2   | UART BRR, Address = 0X04 (BRR) .....                                      | 1011        |
| 38.4.3   | UART SR, Address = 0X10 (SR) .....                                        | 1011        |
| 38.4.4   | UART CR1, Address = 0X14 (CR1) .....                                      | 1012        |
| 38.4.5   | UART CR2, Address = 0X18 (CR2) .....                                      | 1014        |
| 38.4.6   | UART CR3, Address = 0X1C (CR3) .....                                      | 1014        |
| 38.4.7   | UART RAR, Address = 0X20 (RAR) .....                                      | 1015        |
| 38.4.8   | UART TAR, Address = 0X24 (TAR) .....                                      | 1016        |
| 38.4.9   | UART BRRF, Address = 0X28 (BRRF) .....                                    | 1016        |
| 39.      | <b>LOW-POWER UNIVERSAL ASYNCHRONOUS RECEIVERS/TRANSMITTERS (LPUART) .</b> | <b>1017</b> |
| 39.1     | LPUART MAIN FEATURES.....                                                 | 1017        |
| 39.2     | LPUART FUNCTIONAL DESCRIPTION .....                                       | 1018        |
| 39.2.1   | LPUART block diagram .....                                                | 1018        |
| 39.2.2   | LPUART signals .....                                                      | 1018        |
| 39.2.3   | LPUART Character Description .....                                        | 1019        |
| 39.2.4   | LPUART transmission .....                                                 | 1020        |
| 39.2.4.1 | Start bit detection.....                                                  | 1021        |
| 39.2.4.2 | Data character reception .....                                            | 1021        |
| 39.2.4.3 | Special frames and error handling .....                                   | 1022        |
| 39.2.4.4 | Clock source selection.....                                               | 1022        |
| 39.2.4.5 | Framing error.....                                                        | 1023        |
| 39.2.4.6 | Configure the number of stop bits.....                                    | 1023        |
| 39.2.5   | LPUART baud rate generation .....                                         | 1023        |
| 39.2.6   | LPUART reception tolerance.....                                           | 1024        |
| 39.2.7   | LPUART multiprocessor communication .....                                 | 1024        |
| 39.2.7.1 | Idle bus detection .....                                                  | 1024        |
| 39.2.7.2 | 4-bit/7-bit address flag detection.....                                   | 1025        |
| 39.2.8   | LPUART parity.....                                                        | 1025        |
| 39.2.8.1 | Even parity.....                                                          | 1026        |
| 39.2.8.2 | Odd parity .....                                                          | 1026        |
| 39.2.8.3 | Receipt check .....                                                       | 1026        |
| 39.2.8.4 | Transmit parity bit .....                                                 | 1026        |
| 39.2.9   | LPUART single-line half-duplex communication .....                        | 1026        |
| 39.2.10  | DMA continuous communication .....                                        | 1026        |

|           |                                                                      |             |
|-----------|----------------------------------------------------------------------|-------------|
| 39.2.10.1 | Transmission using DMA .....                                         | 1026        |
| 39.2.10.2 | Reception using DMA .....                                            | 1027        |
| 39.2.10.3 | Error flags and interrupts .....                                     | 1028        |
| 39.2.11   | <i>RS232 hardware flow control and RS485 driver enablement .....</i> | <i>1028</i> |
| 39.2.11.1 | RS232 RTS Flow control .....                                         | 1028        |
| 39.2.11.2 | RS232 CTS Flow control .....                                         | 1029        |
| 39.2.11.3 | RS485 Driver Enable .....                                            | 1029        |
| 39.2.12   | <i>LPUART low-power modes .....</i>                                  | <i>1030</i> |
| 39.2.12.1 | Generate an interrupt wake-up request according to WUS .....         | 1030        |
| 39.2.12.2 | Entering low power mode from silent mode .....                       | 1030        |
| 39.2.12.3 | Kernel clock off in low power mode .....                             | 1030        |
| 39.3      | LPUART INTERRUPTS.....                                               | 1031        |
| 39.4      | LPUART REGISTERS .....                                               | 1032        |
| 39.4.1    | <i>LPUART control register 1 (LPUART_CR1) .....</i>                  | <i>1032</i> |
| 39.4.2    | <i>LPUART control register 2 (LPUART_CR2) .....</i>                  | <i>1034</i> |
| 39.4.3    | <i>LPUART control register 3 (LPUART_CR3) .....</i>                  | <i>1035</i> |
| 39.4.4    | <i>LPUARTbaud rate register (LPUART_BRR).....</i>                    | <i>1036</i> |
| 39.4.5    | <i>LPUARTrequest register (LPUART_RQR) .....</i>                     | <i>1037</i> |
| 39.4.6    | <i>LPUARTinterrupt and status register (LPUART_ISR).....</i>         | <i>1037</i> |
| 39.4.7    | <i>LPUARTInterrupt Flag Zero Register (LPUART_ICR) .....</i>         | <i>1039</i> |
| 39.4.8    | <i>LPUARTreceive data register (LPUART_RDR) .....</i>                | <i>1040</i> |
| 39.4.9    | <i>LPUARTSend Data Register (LPUART_TDR).....</i>                    | <i>1040</i> |
| 39.4.10   | <i>LPUARTPrescaler Register (LPUART_PRESC).....</i>                  | <i>1040</i> |
| 40.       | <b>CLOCK TRIMMING CONTROLLER (CTC).....</b>                          | <b>1042</b> |
| 40.1      | INTRODUCTION .....                                                   | 1042        |
| 40.2      | MAIN FEATURES.....                                                   | 1042        |
| 40.2.1    | <i>CAN block diagram .....</i>                                       | <i>1042</i> |
| 40.3      | FUNCTIONAL DESCRIPTION.....                                          | 1043        |
| 40.3.1    | <i>REF synchronous pulse generator.....</i>                          | <i>1043</i> |
| 40.3.2    | <i>CTC calibration counter.....</i>                                  | <i>1043</i> |
| 40.3.3    | <i>Frequency evaluation and automatic calibration process .....</i>  | <i>1044</i> |
| 40.3.4    | <i>Software Programming Guide .....</i>                              | <i>1045</i> |
| 40.4      | REGISTER DESCRIPTION (BASE ADDRESS 0x4000_C800).....                 | 1045        |
| 40.4.1    | <i>CTC Control Register 0 (CTC_CTL0) .....</i>                       | <i>1045</i> |
| 40.4.2    | <i>CTC Control Register 1 (CTC_CTL1) .....</i>                       | <i>1046</i> |

|            |                                                                          |             |
|------------|--------------------------------------------------------------------------|-------------|
| 40.4.3     | CTC status register (CTC_SR).....                                        | 1047        |
| 40.4.4     | CTC interrupt clear register (CTC_INTC).....                             | 1049        |
| <b>41.</b> | <b>RANDOM NUMBER GENERATOR (RNG) .....</b>                               | <b>1050</b> |
| 41.1       | OVERVIEW .....                                                           | 1050        |
| 41.1.1     | Main features .....                                                      | 1050        |
| 41.1.2     | Top-level structure diagram.....                                         | 1050        |
| 41.2       | FUNCTIONAL DESCRIPTION.....                                              | 1051        |
| 41.2.1     | Generation of random numbers .....                                       | 1051        |
| 41.2.2     | Software operation of RNG .....                                          | 1051        |
| 41.2.3     | Random Source of RNG .....                                               | 1051        |
| 41.3       | TIMX REGISTERS.....                                                      | 1051        |
| 41.3.1     | RNG Control Register (RNG_CR).....                                       | 1051        |
| 41.3.2     | RNG linear feedback shift register (RNG_LFSR).....                       | 1052        |
| 41.3.3     | RNG status register (RNG_SR) .....                                       | 1052        |
| 41.3.4     | RNG Data Register (RNG_DR).....                                          | 1052        |
| <b>42.</b> | <b>AES HARDWARE ACCELERATOR (AES).....</b>                               | <b>1054</b> |
| 42.1       | INTRODUCTION .....                                                       | 1054        |
| 42.1.1     | Main Features.....                                                       | 1054        |

## 1. List of abbreviations for registers

| Abbreviation             | Description                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Read/Write (RW)          | Software can read and write to this bit.                                                                                    |
| Read-only (R)            | Software can only read this bit.                                                                                            |
| Write-only (W)           | Software can only write to this bit.                                                                                        |
| Read/ClearWrite0 (RC_W0) | Software can read as well as clear this bit by writing 0. Writing 1 has no effect on this bit.                              |
| Read/ClearWrite1(RC_W1)  | Software can read as well as clear this bit by writing 1. Writing 0 has no effect on this bit.                              |
| Read/ClearWrite(RC_W)    | The software can read and clear the bit by writing to the register. The value written to this bit is not important.         |
| Read/Clearby read (RC_R) | Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value. |
| Read/SetbyRead (RS_R)    | Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.   |
| Read/Set (RS)            | Software can read as well as set this bit by writing 1. Writing 0 has no effect on this bit.                                |
| Toggle (T)               | The software can toggle this bit by writing 1. Writing 0 has no effect.                                                     |
| Reserve (Res)            | Reserved bit, must be kept at reset value.                                                                                  |

## 2. System architecture block

Figure 2-1 System block diagram

### 3. System and memory architecture

The PY32E407-B1 series devices are based on Arm® Cortex® -32-bit general-purpose microcontroller for the-M4F processor. Arm® Cortex® The-M4F processor includes three AHB buses called I-CODE bus, D-Code bus and system bus. Cortex® All storage accesses of the-M4F processor, depending on different destinations and destination storage spaces, will be performed on these three buses. The organization of memory adopts Harvard architecture, pre-defined memory mapping and up to 4 GB of storage space, which fully guarantees the flexibility and scalability of the system.

#### 3.1 Arm® Cortex® -M4F processor introduction

Cortex® The-M4F processor is a 32-bit processor with low interrupt latency time and low-cost debugging features. High integration and enhanced features make Cortex® The-M4F processor is suitable for those market segments that require high-performance and low-power microcontrollers. Cortex® The-M4F processor is based on the Armv7 architecture and supports a powerful and extensible instruction set, including general data processing I/O control tasks, enhanced data processing bit field operations, digital signal processing (DSP) and floating point arithmetic instructions. Listed below by Cortex® Some of the system peripherals supplied by M4F:

- Internal bus matrix for the interconnection of I-Code bus, D-Code bus, system bus, private bus (PPB) and debug private bus (AHB-AP)
- Nested Vector Interrupt Controller (NVIC)
- Flash address reload and breakpoint unit (FPB)
- Data observation point and tracking unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded Tracking Macro Unit (ETM)
- Serial line and JTAG debug interface (SWJ-DP)
- Trace port interface unit (TPIU)
- Memory protection unit (MPU)
- Floating point unit (FPU)

#### 3.2 System architecture

The system adopts a 32-bit multi-layer AHB bus matrix, which can ensure parallel communication between multiple masters and multiple slaves:

- Six main control buses:
  - Cortex® -M4F core I-Code bus, D-Code bus and system bus
  - DMA1 bus
  - DMA2 bus
  - ETH DMA Bus
- Eight controlled buses:
  - Internal Flash I-Code bus
  - Internal Flash D-Code bus
  - Internal SRAM1 bus
  - Internal SRAM2 bus

- Internal CCM SRAM bus
- AHB1 peripheral bus (including AHB to APB bus bridge and APB peripherals)
- AHB2 Peripheral Bus
- ESMC

Figure 3-1 System architecture diagram

### 3.2.1 I\_bus

This bus is used to connect the Cortex® The instruction bus of the-M4F core is connected to the bus matrix. The kernel fetches instructions through this bus. The object accessed by this bus is the memory containing the code (internal Flash/SRAM1/CCM SRAM or external memory via ESMC).

### 3.2.2 D\_bus

This bus is used to connect the Cortex® The-M4F data bus is connected to the bus matrix. The kernel makes immediate digital load and debug access through this bus. The object accessed by this bus is the memory containing code or data (internal Flash/SRAM1/CCM SRAM or external memory via ESMC).

### 3.2.3 S\_bus

This bus is used to connect the Cortex® The system bus of the-M4F core is connected to the bus matrix. This bus is used to access data located in peripherals or SRAM. The objects accessed by this bus are 144 KB of internal SRAM1/SRAM2/CCM SRAM, APB1 peripherals including AHB peripherals, APB2 peripherals, and external memory via ESMC.

### 3.2.4 DMA1/DMA2 BUS

This bus is used to connect the DMA memory bus master interface to the bus matrix. The objects accessed by DMA through this bus are 144 KB of internal SRAM1, SRAM2, CCM SRAM, APB1 peripherals including AHB peripherals, APB2 peripherals, and external memory through ESMC.

### 3.2.5 ETH DMA BUS

This bus is used to connect the ETH DMA memory bus master interface to the bus matrix. The objects accessed by ETH DMA via this bus are 144 KB of internal SRAM1, SRAM2, CCM SRAM, and external memory via ESMC.

### 3.2.6 Bus matrix

The bus matrix is used for access arbitration management between master buses. The arbitration uses a Round Robin algorithm. The system includes 6 Master devices, namely ARM® Cortex® I\_BUS, D\_BUS, S\_BUS, DMA1, DMA2, and ETH DMA of-M4F; And eight Slave devices Slave, which are internal Flash memory, internal SRAM1, SRAM2, CCM SRAM, AHB1 peripheral (peripheral corresponding to AHB2APB bridge 1 and peripheral corresponding to AHB2APB bridge 2), AHB2 peripheral, and ESMC, respectively.

### 3.2.7 AHB/APB bus bridge

With two AHB/APB bus bridges, APB1 and APB2 can achieve a fully synchronized connection between the AHB bus and the two APB buses, allowing flexible peripheral frequency selection.

After each chip reset, all peripheral clocks are turned off (except SRAM and Flash interfaces). Before using a peripheral, its clock must be enabled in the RCC\_AHBxENR or RCC\_APBxENR register.

For AHB and APB peripheral address mapping information, refer to 3.3.2.

## 3.3 Memory organization architecture

### 3.3.1 Introduction

Arm® Cortex® The-M4F processor adopts Harvard architecture and can use independent buses to read instructions and load/store data. The instruction code and data are located in the same memory address space, but in different address ranges. Program memory, data memory, registers, and I/O ports are all within the same linear 4 GB address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

For details on peripheral register mapping, see the relevant sections.

The addressable storage space is divided into 8 main blocks, each of which is 512 MB.

### 3.3.2 Memory map

All other memory space not allocated to on-chip memory and peripherals is reserved address space. Refer to the table below for detailed storage and register space mapping.

The peripherals that can be used in the product and the corresponding address boundaries are given in the table below.

Table 3-1 Memory boundary address

| Type | Boundary Address          | Size      | Memory Area                                                                                        | Description                                                                                                                                                                      |
|------|---------------------------|-----------|----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SRAM | 0x2002 4000 - 0x3FFF FFFF | 511 MB    | Reserved                                                                                           | 1. When the CPU reads and writes to this space, a Response error is generated, and then a HardFault exception is entered<br>2. A TEIF status bit is generated when DMA access.   |
|      | 0x2000 0000 - 0x2002 3FFF | 144 KB    | SRAM                                                                                               | If the hardware power-on configuration SRAM is 144 KB, the SRAM address space is 0x2000 0000-0x20023FFF                                                                          |
| Code | 0x1FFF 8000 - 0x1FFF FFFF | 32 KB     | Reserved                                                                                           | -                                                                                                                                                                                |
|      | 0x1FFF 7E00 - 0x1FFF 7FFF | 512 Bytes | UID bytes                                                                                          | Unique ID                                                                                                                                                                        |
|      | 0x1FFF 7600 - 0x1FFF 7DFF | 2 KB      | Factory config. bytes                                                                              | -                                                                                                                                                                                |

1. AHB in the above table is marked as a **reserved** address space, which cannot be written. The readback is 0, and a Hard fault is generated.

### 3.4 Embedded SRAM

PY32E407-B1 series devices have built-in static SRAM with a maximum of 144 KB bytes. According to different product definitions, the SRAM capacity will vary. Please refer to the data sheet for details. It can be accessed in bytes, half words (16 bits), or full words (32 bits). The start address of the SRAM is 0x2000 0000.

96K SRAM1 (mapped to address 0x2000 0000)

16K SRAM2 (mapped to address 0x2001 8000)

32K CCM SRAM (mapped to address 0x1000 0000 and end 0x2001 C000 of SRAM2)

when boot from SRAM1 is selected or when physical remap is selected, it is accessed by the CPU through I-Code/D-Code bus for maximum performance.

The CCM SRAM SRAM mapped at address 0x1000 0000.

Due to accessed by I-Code bus for maximum performance from CCM SRAM without any remapping.

The CCM SRAM succeeds the address at the end SRAM, providing contiguous address space with SRAM and SRAM.

### 3.4.1 Parity check

The first 32 KB of SRAM1 and the entire CCM SRAM comes with parity.

The user can enable parity using the option bit SRAM\_PE in the user options byte.

The data bus width is 36 bits because 4 bits are available for parity (1 bit per byte).

Parity bits are automatically calculated and stored when written to SRAM. Then, it is automatically checked when reading. If 1 bit fails, an NMI end interrupt is generated. Errors can also be linked to BRK\_IN of TIM1/TIM8/TIM15/TIM16/TIM17.

Note: When SRAM parity is enabled, it is recommended to initialize the SRAM with software to avoid parity errors when reading.

### 3.4.2 CCM SRAM Write Protection

CCM SRAM can be write-protected with a page granularity of 1 K bytes.

Write protection can be enabled in the SYSCFG CCM SRAM write protection register (SYSCFG\_SWPR) in SYSCFG. This is a register with a one-time write "1" mechanism, which means that "write protection" is set for this page of SRAM by a one-time write "1" and this setting can only be cleared by a system reset.

Table 3-3 CCM SRAM configuration

| Page number | Start address             | End address               |
|-------------|---------------------------|---------------------------|
| Page 0      | 0x1000 0000 / 0x2001 C000 | 0x1000 03FF / 0x2001 C3FF |
| Page 1      | 0x1000 0400 / 0x2001 C400 | 0x1000 07FF / 0x2001 C7FF |

### 3.4.3 CCM SRAM Read protection

The CCM SRAM has read protection (RDP). For more information, see 4.10.1: Flash Read Protection (RDP).

### 3.4.4 CCM SRAM Erasure

The CCM SRAM may use the option configuration bit CCMSRAM\_RST to erase the content at the time of reset (refer to 4.8.1 the Flash option byte description). The CCMSR control bit implementation can also be set using software methods (refer to 10.2.22 the SYSCFG CCM SRAM Control and Status Register (SYSCFG\_SCSR)).

## 3.5 Embedded Flash

Flash memory consists of two different physical areas:

- The Main flash area, 512 KB, consists of two Banks, which contain application and user data. According to different product definitions, Flash capacity will vary. Please refer to the data sheet for details. Used to store user programs and user data. Software access to space outside the set range will produce a Hard fault.
- Information area, 32 KB, consists of the following sections:
  - Factory config. bytes: 2048 Bytes
  - UID: 512 Bytes, used to store the UID of the chip
  - OTP: 1024 Bytes, used to store user OTP data
  - Option bytes: 256 Bytes, used to store configuration values for chip hardware and storage protection
  - System memory: 28 KB for the Boot loader

Flash interface realizes instruction reading and data access based on AHB protocol, and it realizes the basic program/erase operations of Flash through registers.

## 3.6 Bit segment

Cortex® The-M4F memory map includes two bit segment regions. These regions map each word in the memory alias region to a corresponding bit in the memory bit segment region. When a word is written in the alias area, it is equivalent to performing a read-modify-write operation on the target bit of the bit segment area.

In the PY32E407-B1 device, both peripheral registers and SRAM are mapped to a bit region, which enables read and write operations of a single bit region. These operations are only available for Cortex® -M4F access, not valid for other bus master interfaces such as DMA.

The correspondence between each word in the alias region and each bit in the bit segment region may be described by a mapping formula. The mapping formula is:

$$\text{Bit\_word\_addr} = \text{bit\_band\_base} + (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)$$

with:

- Bit\_word\_addr represents the address of the word that will be mapped to the target bit in the alias area
- Bit\_band\_base represents the starting address of the alias zone
- Byte\_offset represents the byte number in the bit segment area where the target bit is located
- Bit\_number represents the bit position of the target bit (0-7)

#### example

The following example illustrates how to map bit 2 of a byte at SRAM address 0x2000 0300 to an alias region:

$$0x2200\ 6008 = 0x2200\ 0000 + (0x300 \times 32) + (2 \times 4)$$

Performing a write operation to address 0x2200 6008 is equivalent to performing a read-modify-write operation at bit 2 of the byte at SRAM address 0x2000 0300.

Performing a read operation to address 0x2200 6008 will return the value of bit 2 of the byte at SRAM address 0x2000 0300 (0x01 for position bit, 0x00 for bit reset).

For more information about bit segments, see Cortex® -M4F Programming Manual (DUI508B\_cortex\_m4\_ugrm.pdf).

## 3.7 Start Configuration

By configuring the bits BOOT0 pin, nBOOT0/nBOOT1/nSWBOOT0 (stored in option bytes), you can select three different boot modes, as shown in the following table:

Table 3-4 Boot configuration

| BOOT_Lock | Boot mode configuration  |                           |                  |                             | Mode                   |
|-----------|--------------------------|---------------------------|------------------|-----------------------------|------------------------|
|           | nBOOT1<br>FLASH_OPTR2[8] | nBOOT0<br>FLASH_OPTR2[14] | BOOT0<br>Pin PB8 | nSWBOOT0<br>FLASH_OPTR2[13] |                        |
| 1         | X                        | X                         | X                | X                           | Boot from Main flash   |
| 0         | X                        | X                         | 0                | 1                           | Boot from Main flash   |
| 0         | X                        | 1                         | X                | 0                           | Boot from Main flash   |
| 0         | 0                        | X                         | 1                | 1                           | Boot from SRAM1        |
| 0         | 0                        | 0                         | X                | 0                           | Boot from SRAM1        |
| 0         | 1                        | X                         | 1                | 1                           | Boot from System flash |
| 0         | 1                        | 0                         | X                | 0                           | Boot from System flash |

The Boot loader program is stored in the System memory and is used to download Flash programs through USART, USB, SPI, and I<sup>2</sup>C interfaces.

After system reset, the value of the BOOT0 pin or the user option configuration bit (depending on the value of the nSWBOOT0 bit in the FLASH\_OPTR register) and the nBOOT1 bit are latched. When you exit from standby mode, the value of the BOOT pin will be re-latched; Therefore, the BOOT pin should remain in the required BOOT configuration in standby mode.

Depending on the selected boot mode, the main flash memory, the system memory, or the SRAM 1 may be accessed in the following manner:

- Boot from the main flash memory: The main flash memory is mapped to the boot space (0x0000

0000), but it can still be accessed at its original address (0x0800 0000), i.e. the contents of the flash memory can be accessed in two address areas, 0x0000 0000 or 0x0800 0000.

- Boot from system memory: System memory is mapped to boot space (0x0000 0000), but it can still be accessed at its original address (0x1FFF 0000).
- Boot from built-in SRAM1: SRAM1 is mapped to the boot space (0x0000 0000), but it can still be accessed at its original address (0x2000 0000).

After boot, the CPU acquires the address at the top of the stack from the address 0x0000 0000, and starts executing code from the address indicated by 0x0000\_0004 of the boot memory. Because of the fixed memory image, the code area always starts at address 0x0000\_0000 (accessed via the ICode and DCode buses), while the data area (SRAM) always starts at address 0x2000\_0000 (accessed via the system bus). The CPU of the Cortex M4F always gets the reset vector from the ICode bus, i.e. boot is only suitable for starting from the code area (typically boot from Flash). The PY32E407-B1 series microcontrollers implement a special mechanism that can be booted from on-chip SRAM. When booting from on-chip SRAM, in the initialization code of the application, the NVIC's exception table and offset register must be used to remap the vector table into SRAM.

### 3.7.1 System Storage Startup

The system memory contains an embedded boot loader that can be used to program the flash memory. The boot loader reprograms the flash memory through the USART or USB interface.

### 3.7.2 Physical remap

When the boot pin is selected, the application software can set some memory to be accessed from the code space (so that code can be executed over the ICode bus instead of the system bus). Such modifications are achieved by programming SYSCFG.MEM\_ MODE in the SYSCFG controller. The following memories can thus be remapped:

- Main flash
- System memory
- Embedded SRAM1
- ESMC

Table 3-5 Physical remapping address

| Address                   | Main Flash Start/Remap | Embedded SRAM1 Start/Remap | System memory Start/Remap             | ESMC Remapping |
|---------------------------|------------------------|----------------------------|---------------------------------------|----------------|
| 0x2000 0000 - 0x2001 7FFF | SRAM1                  | SRAM1                      | SRAM1                                 | SRAM1          |
| 0x1FFF 0000 - 0x1FFF 7FFF | System memory          | System memory              | System memory                         | System memory  |
| 0x0808 0000 - 0x0FFF FFFF | Reserved               | Reserved                   | Reserved                              | Reserved       |
| 0x0800 0000 - 0x0807 FFFF | Flash                  | Flash                      | Flash                                 | Flash          |
| 0x0400 0000 - 0x07FF FFFF | Reserved               | Reserved                   | Reserved                              | ESMC           |
| 0x0000 0000 - 0x03FF FFFF | Flash (using aliases)  | SRAM1 (using aliases)      | System memory (28 KB) (using aliases) | ESMC           |

## 4. Embedded Flash interface

### 4.1 Introduction

The Flash interface can manage the CPU to access Flash through the AHB I-Code and D-Code buses.

The interface can be executed against Flash

Erase and program operations, and implement read and write protection mechanisms.

The Flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

### 4.2 Main Features

- Memory organization:
  - Main memory: Up to 512 KB
  - Information memory: 32 KB
  - Page size: 512 Bytes
  - Sector size: 4 KB
  - Block size: 64 KB
  - 137-bit wide data read (128 bits data+9 bits ecc)
  - 137-bit wide data write (128 bits data+9 bits ecc)
- Flash read operation
- Flash programming operations (page programming)
- Flash erase operation (page erase/sector erase/block erase/full erase)
- Read/write protection
- Prefetch operations on I-Code
- Branch caching on I-Code
- Data caching on D-Code
- Option byte loading function

### 4.3 Flash memory organization

Flash memory consists of a 137-bit wide (128 bits data + 9 bits ecc) cell, has a dual-Bank architecture that supports read-write function (RWW), and can be used as storage for programs and data. Page size is 512 Bytes, Sector size is 4 KB, and Block size is 64 KB.

Functionally, Flash memory is divided into Main flash and Information flash. The former has a maximum capacity of 512 KB, and the latter has a capacity of 32 KB, as follows:

Table 4-1 Flash memory structure and boundary address

| Area        | Space Name |         |           |              | Address                   | Size (bytes) |
|-------------|------------|---------|-----------|--------------|---------------------------|--------------|
| Main memory | Bank0      | Block 0 | Sector 0  | Page 0-7     | 0x0800 0000 - 0x0800 0FFF | 4 °K         |
|             |            |         | Sector 1  | Page 8-15    | 0x0800 1000 - 0x0800 1FFF | 4 °K         |

## 4.4 Error code correction (ECC)

The data in the flash memory is 137 bits: each 128 bits add 9 bits ECC.

The ECC mechanism supports:

- One-bit error detection and correction
- Two-bit error detection

When a one-bit error is detected and corrected, the flag ECCC (ECC Correction) is set in the FLASH\_ECCR register. If ECCIE is also set, an interrupt will be generated.

When a two-bit error is detected, the flag ECCD (ECC detection) is set in the FLASH\_ECCR register. In this case, an NMI interrupt is generated.

When an ECC error is detected, the failure address and its associated Bank are saved in ADDR\_ECC, SYSF\_ECC, and BK\_ECC in the FLASH\_ECCR register.

When ECCC or ECCD is set, ADDR\_ECC, SYSF\_ECC, and BK\_ECC are not updated if a new ECC error occurs. FLASH\_ECCR is updated only after the ECC flag is cleared.

Note: When accessing the initial data: 0x1FF FFFF FFFF FFFF FFFF FFFF FFFF FFFF, a one-bit error is detected and corrected.

## 4.5 Read access latency

In order to correctly read instructions/data from the Flash memory, it is necessary to set the number of waiting cycles (Latency) of the register Flash\_ACR according to the frequency of the CPU clock (HCLK).

After chip reset (including power-on reset, system reset, and exit Standby reset), the HCLK clock frequency is 16 MHz and the number of Flash read cycles is 0.

When changing the CPU clock frequency or range, you must follow the following software steps to adjust the number of waiting cycles required to access Flash memory.

### Operation steps when increasing CPU frequency

1. Program a new number of wait cycles to the LATENCY bit in the FLASH\_ACR register
2. Check whether the new waiting period is set successfully by reading the FLASH\_ACR register
3. Modify the CPU clock source by overwriting the SW bit in the RCC\_CFGR register
4. If necessary, the CPU clock prescaler can be modified by rewriting the HPRE bit in the RCC\_CFGR
5. By reading the corresponding clock source state (SWS bit) and/or AHB prescalation value in the RCC\_CFGR register

(HPRE bit), check whether the new CPU clock source and/or the new CPU clock prescalation value is successfully set

### Operation procedures when reducing CPU frequency

1. Modify the CPU clock source by overwriting the SW bit in the RCC\_CFGR register
2. If necessary, the CPU clock prescaler can be modified by rewriting the HPRE bit in the RCC\_CFGR
3. By reading the corresponding clock source state (SWS bit) and/or AHB prescalation value in the RCC\_CFGR register  
(HPRE bit), check whether the new CPU clock source and/or the new CPU clock prescalation value is successfully set
4. Program the new number of waiting cycles to the LATENCY bit in FLASH\_ACR
5. Check whether the new waiting period is set successfully by reading the FLASH\_ACR register

## 4.6 Adaptive real-time memory accelerator

Proprietary Adaptive Real Time (ART) Memory Accelerator for ARM® Cortex® The-M4F processor is optimized. This accelerator well embodies the inherent performance advantages of ARM Cortex M4F, and overcomes the situation that high-speed processors often need to wait for FLASH reading during operation under normal conditions.

In order to give full play to the performance of the processor, the accelerator will implement instruction prefetch queue and branch cache, thus improving the program execution speed of 128-bit Flash. According to the CoreMark benchmark, the performance obtained with the ART accelerator is equivalent to Flash executing programs with 0 wait cycles at CPU frequencies up to 170 MHz.

### ■ Instruction prefetch

Each Flash read operation can read 128 bits, which can be 4 lines of 32-bit instructions or 8 lines of 16-bit instructions, depending on the program programmed in Flash. Therefore, for sequentially executed code, it takes at least 4 CPU cycles to execute the previously read 128-bit instruction line. When the CPU requests the current instruction line, the prefetch operation of the I-Code bus can be used to read the next consecutively stored 128-bit instruction line in Flash.

### ■ Instruction cache memory

In order to reduce the time loss caused by instruction jumping, 64 lines of 128-bit instructions can be saved to the instruction cache memory. Whenever an instruction is missing (i.e., the requested instruction does not exist on the currently used instruction line, prefetch instruction line, or instruction cache memory), the system copies the newly read line into the instruction cache memory. If the instruction requested by the CPU already exists in the instruction buffer, it can be fetched immediately without any delay. After the instruction cache memory is full, the LRU (Least Recently Used) policy can be used to determine the instruction line to be replaced in the instruction cache memory. This feature is particularly useful in case of code containing loops.

### ■ Data management

During the CPU pipeline execution phase, the data buffer in Flash will be accessed through the D-Code bus. The CPU pipeline will only continue to execute after it obtains the requested data. In order to reduce the resulting time loss, access via the AHB data bus D-Code takes precedence over access via the AHB instruction bus I-Code. This feature works similarly to instruction cache memory, but the reserved data size is limited to 8 lines and 128 bits.

## 4.7 Erasure and program operations

Flash can be programmed through ICP (In-circuit programming) or IAP (In-application programming).

ICP: Used to update the contents of the entire Flash memory, you can use the JTAG/SWD protocol or Boot loader,  
Load the user application into the MCU.

IAP: You can use the communication interface supported by the chip to download the data to be programmed into Flash. IAP allows the user to program flash memory again while the application is running.

If a reset occurs during a Flash program or erase operation, the contents of the Flash memory are not protected.

During a program or erase operation on one Bank, read access can be made to another Bank. Hard fault will be generated when reading and writing BANK in the program or erase operation.

HSI must be turned on for program and erase operations.

#### 4.7.1 Unlocking the Flash memory

After reset, the Flash control register (Flash\_CR) does not allow write operations to prevent unexpected operations on the Flash due to electrical interference or the like. Each erase and program operation on Flash must be unlocked by writing Flash\_KEYR to enable access to the Flash\_CR register.

This is done in the following steps:

Step 1: Write KEY1 = 0x4567 0123 to the FLASH\_KEYR register

Step 2: Write KEY2 = 0xCDEF 89AB to the FLASH\_KEYR register

Any mistiming locks the FLASH\_CR register until the next reset. At the wrong KEY timing, a bus Hard fault interrupt will be generated. Such errors include a KEY1 mismatch for the first write cycle, or a KEY1 match but a KEY2 mismatch for the second write cycle.

The FLASH\_CR register may be locked again by software writing the LOCK bit of the FLASH\_CR register.

Note: When the BSY bit of the FLASH\_SR register is set, the FLASH\_CR register cannot be written.

#### 4.7.2 Flash memory erase

Flash erase operation supports page, sector, block, bank erase, and does not work on information memory when Bank0 erase is executed.

##### 4.7.2.1 Flash page erasure

The Page erase is used to erase the 512 Bytes Main flash, but it does not work for the Information area.

When a page is protected by WRP, it will not be erased. At this time, the WRPERR bit is set.

The specific steps of the page erase operation are as follows:

- 1) Check the BSY bit of the flash\_SR register to confirm that there is no flash operation in progress
- 2) Write KEY1 and KEY2 to the FLASH\_KEYR register in turn to release the protection of the FLASH\_CR register
- 3) Set the PER bit and EOPIE bit of the FLASH\_CR register
- 4) Write arbitrary data to this page (must be 32-bit data)
- 5) Wait for the BSY bit to be cleared

- 6) Check that the EOP flag bit is set
- 7) Clear the EOP flag

#### **4.7.2.2 Flash sector erase**

Sector erase is used to erase the 4 KB Main flash, but it does not work for the Information area.

When a sector is protected by WRP, it will not be erase. At this time, the WRPERR bit is set.

The specific steps of the sector erase operation are as follows:

- 1) Check the BSY bit to confirm whether there is no ongoing Flash operation
- 2) Write KEY1 and KEY2 to that FLASH\_KEYR register in turn to release the protection of the FLASH\_CR register
- 3) Set the SER bit and EOPIE bit of the FLASH\_CR register
- 4) Write arbitrary data to this sector (must be 32-bit data)
- 5) Wait for the BSY bit to be cleared
- 6) Check that the EOP flag bit is set
- 7) Clear the EOP flag

#### **4.7.2.3 Flash block erasure**

The Block erase is used to erase the 32 KB Main flash, but does not work for the Information area.

When a Block is protected by WRP, it will not be erase. At this time, the WRPERR bit is set.

The specific steps of block erase operation are as follows:

- 1) Check the BSY bit to confirm whether there is no ongoing Flash operation
- 2) Write KEY1 and KEY2 to that FLASH\_KEYR register in turn to release the protection of the FLASH\_CR register
- 3) Set the BER bit and EOPIE bit of the FLASH\_CR register
- 4) Write arbitrary data to this block (32 bits data must be)
- 5) Wait for the BSY bit to be cleared
- 6) Check that the EOP flag bit is set
- 7) Clear the EOP flag

#### **4.7.2.4 Flash Bank Erasure**

Bank erase is used to erase the 256 KB Main flash, but it does not work for the Information area.

When WRP is enabled, the Bank erase function is invalid, no Bank erase operation is generated, and the WRPERR bit is set.

The specific steps of Bank erase operation are as follows:

- 1) Check the BSY bit to confirm whether there is no ongoing Flash operation
- 2) Write KEY1 and KEY2 to that FLASH\_KEYR register in turn to release the protection of the FLASH\_CR register
- 3) Set the MER1 bit or MER0 bit and the EOPIE bit of the FLASH\_CR register
- 4) Write any data to any Flash space corresponding to Bank Flash (32 bits data must be required)
- 5) Wait for the BSY bit to be cleared
- 6) Check that the EOP flag bit is set
- 7) Clear the EOP flag

### **4.7.3 Flash memory programming**

Flash memory is performed in units of 32 bits (word) each time (a half word or byte operation will generate a Hard fault)

program operation for the entire page. When the PG bit of the Flash\_CR register is set and the CPU writes 32 bits of data to the Flash memory address space, the program operation starts.

If the flash address space to be programmed is an area set to protect by the flash\_WRP register, then

The program operation is ignored and the WRPRTERR bit of the FLASH\_CR register is set. Knots of Program operations

Bundle, the EOP bit of the FLASH\_CR register is set.

The specific operation steps of the Flash program are as follows:

- 1) Check the BSY bit of the Flash\_SR register to determine whether there is currently no continuing Flash operation
- 2) If there is no ongoing Flash erase or program operation, the software reads out 128 of the Page word (if you need to keep the data already existing on this page, perform this step, otherwise skip this step)
- 3) Write KEY1 and KEY2 to the FLASH\_KEYR register in turn to release the protection of the FLASH\_CR register
- 4) Set the PG bit and EOPIE bit of the FLASH\_CR register
- 5) Perform the 1st to 127th word program operations to the target address (only 32-bit programs are accepted)
- 6) Set the PGSTRT of the FLASH\_CR register
- 7) Write the 128th word
- 8) Wait for the BSY bit of the FLASH\_SR register to be cleared
- 9) Check the EOP flag bit of the FLASH\_SR register (this bit is set when the program operation has been successful), and then  
Software clears this bit
- 10) If there is no more program operation, the software clears the PG bit

When the above step 7) is successfully executed, the program operation is automatically started and the BSY bit is set by the hardware.

## 4.8 FLASH option bytes

### 4.8.1 Flash option byte description

Part of the Flash Information area in the chip is used as an option byte, which is used to store the configuration of the chip or the hardware required by the user for the application. As a configuration example, the watchdog may be selected in hardware or software mode.

For data security, option bytes are stored separately in positive code and negative code form.

Table 4-2 Options byte format

|                            |    |    |    |    |    |    |    |                            |    |    |    |    |    |    |    |
|----------------------------|----|----|----|----|----|----|----|----------------------------|----|----|----|----|----|----|----|
| 31                         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23                         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Option byte 1 inverse code |    |    |    |    |    |    |    | Option byte 0 inverse code |    |    |    |    |    |    |    |
| 15                         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7                          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Option byte 1              |    |    |    |    |    |    |    | Option byte 0              |    |    |    |    |    |    |    |

The contents of the option bytes can be read from the memory addresses described in the option byte structure in Table 4-3, or from the registers associated with the following option bytes:

- Flash user options register 1 (Flash\_OPTR1)
- Flash user options register 2 (Flash\_OPTR2)
- Flash WRP area address register (FLASH\_WRPTR)
- Flash PCROP0SR address register (FLASH\_PCROP0SR)
- Flash PCROP0ER address register (FLASH\_PCROP0ER)
- Flash PCROP1SR address register (FLASH\_PCROP1SR)
- Flash PCROP1ER address register (FLASH\_PCROP1ER)

Table 4-3 Options byte structure

| Word Address | Description                                        |
|--------------|----------------------------------------------------|
| 0x1FFF 7400  | User options byte 1 and inverse code               |
| 0x1FFF 7404  | User options byte 2 and inverse code               |
| 0x1FFF 7408  | Reserved                                           |
| 0x1FFF 740C  | WRP address option byte and complemented code      |
| 0x1FFF 7410  | PCROP0SR Address Option Byte and complemented code |
| 0x1FFF 7414  | PCROP0ER Address Option Byte and complemented code |
| 0x1FFF 7418  | PCROP1SR Address Option Byte and complemented code |
| 0x1FFF 741C  | PCROP1ER Address Option Byte and complemented code |
| ...          | Reserved                                           |
| 0x1FFF 74FF  | Reserved                                           |

#### 4.8.1.1 Option bytes for Flash user option 1

Flash memory address: 0x1FFF 7400

Production value: 0x0955 F6AA

After the power-on reset (POR/OBL\_LAUNCH) is released, the corresponding value is read from the option byte area of the Flash information memory and written to the corresponding option bit of the register.

#### 4.8.1.2 Option bytes for Flash user option 2

Flash memory address: 0x1FFF 7404

Production value: 0x80FF 7F00

After the power-on reset (POR/OBL\_LAUNCH) is released, the corresponding value is read from the option byte area of the flash information memory and written to the corresponding option bit of the register.

#### 4.8.1.7 Option bytes for Flash PCROP1ER address

Flash memory address: 0x1FFF 741C

Production value: 0xFFFF 0000

After the power-on reset (POR/OBL\_LAUNCH) is released, the corresponding value is read from the option byte area of the flash information memory and written to the corresponding option bit of the register.

#### 4.8.2 Flash Option Byte Write

After reset, the bits associated with the option bytes in the FLASH\_CR register are write-protected. The OPTLOCK bit in the FLASH\_CR register must be cleared before relevant operations can be performed on the option byte.

The following steps are used to unlock the register:

1. The write protection of the FLASH\_CR register is released by the unlocking process
2. Write OPTKEY1 = 0x0819 2A3B to the FLASH\_OPTKEYR register
3. Write OPTKEY2 = 0x4C5D 6E7F to the FLASH\_OPTKEYR register

Any wrong sequence locks up the FLASH\_CR register until the next reset. A bus Hard Fault interrupt is generated at the wrong KEY timing.

The User option (the option byte of information flash) can be protected from unwanted erase/program operations by writing the OPTLOCK bit of the FLASH\_CR register by software.

If the software sets the Lock bit, the OPTLOCK bit is also automatically set.

##### 4.8.2.1 Modify option bytes

The program operation of the option byte is different from the operation of Main flash. To modify the option bytes, the following steps are needed:

1. Clear the OPTLOCK bit using the previously described steps
2. Check the BSY bit to confirm that there are no ongoing Flash operations
3. Write the desired value (1 to 7 words) to the option byte register FLASH\_OPTR1/FLASH\_OPTR2/FLASH\_WRPR/FLASH\_PCROR0SR/FLASH\_PCROR0ER/FLASH\_PCROR1SR/FLASH\_PCROR1ER
4. Set the OPTSTRT bit and the EOPIE bit
5. Write arbitrary data to 0x1FFF7400 address (32 bits data is required)
6. Wait for the BSY bit to be cleared.
7. Check that EOP flag bit is set
8. Clear EOP flags

For any changes to the option byte, the hardware will first erase the entire page corresponding to the option byte, and then write the values of the FLASH\_OPTR1, FLASH\_OPTR2, FLASH\_WRPR, FLASH\_PCROR0SR, FLASH\_PCROR0ER, FLASH\_PCROR1SR, and FLASH\_PCROR1ER register into the option byte. Furthermore, the hardware automatically calculates the corresponding complement and writes the calculated value to the corresponding area of the option byte.

#### 4.8.2.2 Load location bytes

After the BSY bit is cleared, all new option bytes are written to the Flash information memory, but are not applied to the system. A read operation on the option byte register still returns the value in the last loaded option byte. Only when they (new values) are loaded do they work on the system.

The loading of option bytes occurs in the following two cases:

- When the OBL\_LAUNCH bit in the FLASH\_CR register is set
- After Power On Reset (POR)

The operation performed by loading option byte is to read the option byte in the information memory area, and then store the read data in the internal option register (FLASH\_OPTR1, FLASH\_OPTR2, FLASH\_WRPR, FLASH\_PCROR0SR, FLASH\_PCROR0ER, FLASH\_PCROR1SR, FLASH\_PCROR1ER).

Each option bit has a corresponding complement at its same double word address (the next half word). During the option byte load, the option bit and its inverse code are verified to ensure that the load is done correctly.

If the positive and negative codes match, the option bytes are copied into the option register.

If the word and its complement are not matching, the OPTVERR status bit of the FLASH\_SR register is set. The mismatched values are written to the option register:

- For OPTR
  - The RDP bit is written as 0xff (i.e. level 1)
  - BFB is written as 0 (i.e. no bank exchange)
  - The rest of the mismatched values are written as 1
- For WRP option, the mismatched value is the default value "Unprotected"
- For the PCROP option, the mismatched value is the default value "All Flash Protection"

After the system reset, the contents of the option byte are copied to the following option register (software readable and writable):

- FLASH\_OPTR1
- FLASH\_OPTR2
- FLASH\_WRPR
- FLASH\_PCROP0SR
- FLASH\_PCROP0ER
- FLASH\_PCROP1SR
- FLASH\_PCROP1ER

These registers are also used to modify option bytes.

## 4.9 Flash user OTP byte

A partial section of the Flash information area in the device is referred to as Flash USER OTP memory Bytes.

There are 2 Pages in total, and each Page is controlled separately.

Table 4-4 USER OTP Structure

| Page | Word                    | Address     | Contents                                                            |
|------|-------------------------|-------------|---------------------------------------------------------------------|
| 1    | 0                       | 0x1FFF 7000 | Bit [31:16]: Deposit user data<br>Bit [15: 0]: USER OTP MEMORY_LOCK |
|      | 1                       | 0x1FFF 7004 | Store user data                                                     |
|      | ...                     | ...         | Store user data                                                     |
|      | 127 COMP block diagram. | 0x1FFF 71FC | Store user data                                                     |
| 2    | 0                       | 0x1FFF 7200 | Bit [31:16]: Deposit user data<br>Bit [15: 0]: USER OTP MEMORY_LOCK |
|      | 1                       | 0x1FFF 7204 | Store user data                                                     |
|      | ...                     | ...         | Store user data                                                     |
|      | 127 COMP block diagram. | 0x1FFF 73FC | Store user data                                                     |

These two Pages are arranged in the information area, and the program and erase of this Page area are processed according to the method of Main flash. In addition, the mass erase of the Main Flash area is not valid for this area.

Set that the content of USER OTP MEMORY\_LOCK will not be updated immediately until the power-on reset (POR/PDR), which will play a protection function.

This Page Write has the following protection.

Table 4-5 Flash USER OTP write protection

| USER OTP MEMORY_LOCK      | Write protection                   |
|---------------------------|------------------------------------|
| 0xAA55                    | Read: Yes<br>Program and erase: No |
| Any value except (0xAA55) | Read, Program and erase: Yes       |

## 4.10 Flash protection

The protection of Main flash area includes the following mechanisms:

- Read protection (RDP), which prevents access from outside.
- Write protection (WRP) control to prevent unwanted write operations (due to clutter of program memory pointer PC). The size of write protection is designed to be 32 KB.
- Option byte write protection, has a dedicated unlocking design.

### 4.10.1 Flash Read Protection (RDP)

The read protection function can be activated by setting the RDP option byte and performing a system reset (POR or OBL reset) to load a new RDP option byte. RDP protects flash main memory, CCM SRAM, and backup registers.

If the read protection is set while the debug through the SWD is still connected, a power-on reset is required instead of a system reset.

Flash memory is protected when the RDP option byte and the inverse code exist correctly in pairs in the option byte.

Table 4-6 Flash read protection status

| RDP option byte value                            | RDP option byte inverse code value | Equal protection level |
|--------------------------------------------------|------------------------------------|------------------------|
| 0xAA                                             | 0x55                               | Level 0                |
| Any value except the combination of [0xAA, 0x55] |                                    | Level 1                |

System memory is readable regardless of the protection level, but it cannot perform program and erase operations.

#### 4.10.1.1 Level 0: no protection

Read, program, and erase operations on the Main flash are possible, as are any operations on option bytes, CCM SRAM, and backup registers.

#### 4.10.1.2 Level 1: Read protection

If the RDP and its inverse code in the option byte contain any combination other than [0xAA, 0x55], Level 1 read protection takes effect, and Level 1 is the default protection level.

- User mode: A program executed in User mode (boot from Main flash) that can do all operations on the Main flash, option bytes, CCM SRAM and backup registers.
- debug, boot from SRAM, boot from system memory modes: In debug mode, or when booting from SRAM or system memory, main flash, CCM SRAM And backup registers are not accessible. In these modes, a read or write access to the main flash results in a bus hard fault interrupt.

The read protection level can be changed:

- From Level 0 to Level 1, change the value of the RDP byte to anything except 0xAA
- Change the value of the RDP byte to 0xAA from Level 1 to Level 0

Level 1 changes to Level 0, which triggers the hardware mass erase Main flash.

Table 4-7 Relationship of access status to protection level and execution mode

| Area             | Protection level | User execution (BootFromFlash) |       |       | Debug/BootFromRam/BootFromLoader |       |       |
|------------------|------------------|--------------------------------|-------|-------|----------------------------------|-------|-------|
|                  |                  | Read                           | Write | Erase | Read                             | Write | Erase |
| Main memory      | 0                | Yes                            | Yes   | Yes   | Yes                              | Yes   | Yes   |
|                  | 1                | Yes                            | Yes   | Yes   | No                               | No    | No    |
| System memory    | x                | Yes                            | No    | No    | Yes                              | No    | No    |
| Option bytes     | x                | Yes                            | Yes   | N/A   | Yes                              | Yes   | N/A   |
| OTP              | x                | Yes                            | Yes   | Yes   | Yes                              | Yes   | Yes   |
| Backup registers | 0                | Yes                            | Yes   | Yes   | Yes                              | Yes   | Yes   |
|                  | 1                | Yes                            | Yes   | Yes   | No                               | No    | No    |
| CCM SRAM         | 0                | Yes                            | Yes   | Yes   | Yes                              | Yes   | Yes   |
|                  | 1                | Yes                            | Yes   | Yes   | No                               | No    | No    |

Notes:

- (1) The Information zone is read-only, regardless of protection level and execution mode.
- (2) A modification of the RDP from Level 1 to Level 0 triggers a mass erase of the hardware to the Main flash.
- (3) There are two situations for executing programs from SRAM or system memory:

One is boot from, the other is boot from another memory, and the program jumps to SRAM or system memory for execution.

#### 4.10.2 Flash Write Protection (WRP)

Flash can be set to write-protected for unwanted write operations. Define a write-protected (WRP) area with a control granularity of 64 KB per bit of the WRP register, that is, 1 block size. See the description of the WRP register for details.

When the WRP area is activated, no erase or program operation is allowed. Accordingly, even if only one area is set to write protection, the bank erase function does not function. In addition, if an attempt is made to perform an erase or program operation on a write-protected area, the write-protected error identifier (WRPERR) of the FLASH\_SR register is set.

Note: Write protection only works for Main flash, not system memory.

#### 4.10.3 Proprietary Code Readout Protection (PCROP)

In addition to flash memory, it can also prevent reading and writing from third parties. The protected area is execution-only: it can only be accessed by the CPU as instruction code, while all other access (DMA, debugging and CPU data reading, writing and erasing) is strictly prohibited. When the RDP protection is changed from level 1 to level 0, the inclusive PCROP area is also erased (see Changing the Read Protection Level).

Each PCROP area is defined by a start page and an end page address associated with a physical flash address. These addresses are defined in the PCROP address registers FLASH\_PCROPSR, FLASH\_PCROP1SR, FLASH\_PCROP end address register (FLASH\_PCROPOER, FLASH\_PCROP1ER).

Any read access performed over the D-code bus to the PCROP protected area will trigger an RDERR flag error.

Any PCROP-protected address is also write-protected, and any write access to one of these addresses triggers WRPERR.

Any PCROP areas are also erase protected. Therefore, any erasure of pages in this area is not possible (including pages containing the start and end addresses of this area). Furthermore, software Bank Mass erasure cannot be performed if an area is protected by PCROP.

PCROP can only be disabled if the RDP is changed from level 1 to level 0. If you attempt to clear the PCROP or narrow the PCROP area by modifying the user options, you can start the option programming, but the PCROP area remains unchanged. Instead, the PCROP region can be increased.

Table 4-8 PCROP Protection

| PCROPx register value (x = 0, 1) | PCROP Protected Area                                   |
|----------------------------------|--------------------------------------------------------|
| PCROPxSR > PCROPxER              | No PCROP area.                                         |
| PCROPxSR ≤ PCROPxER              | The region between PCROPxSR and PCROPxER is protected. |

#### 4.10.4 Forced Boot from Main flash

For increased security, the BOOT\_LOCK option bit of the FLASH\_OPTR2 register allows the system to be forced to boot from the main flash memory, ignoring other boot options. Reset BOOT\_LOCK only if:

- RDP set to Level 0

- RDP Level 1 modified to Level 0

## 4.11 Flash interrupt

Table 4-9 Flash interrupt request

| Interrupt event  | Event flag | Time flag/interrupt clearing | Control bit enable |
|------------------|------------|------------------------------|--------------------|
| End of operation | EOP        | Write EOP=1                  | EOPIE              |
| Write protection | WRPERR     | Write WRPERR=1               | ERRIE              |
| Read error       | RDERR      | Write RDERR=1                | RDERRIE            |
| ECC correction   | ECCC       | Write ECCC=1                 | ECCIE              |

The following event does not have a separate break identity, but produces a Hard fault:

- Flow error unlocking FLASH\_CR register for Flash memory
- Write operation flow error to unlock Flash option byte
- Flash program, erase operation fails to align 32-bit data
- Read and write access to Bank in program, erase
- In one Bank program, erase, another Bank program, erase

## 4.12 TIMx registers

### 4.12.1 Flashaccesscontrol register (Flash\_ACR)

### 4.12.2 Flashkey register (Flash\_KEYR)

**Address offset:** 0x08

**Reset value:** 0x0000 0000

All register bits are write-only and the read returns 0.

#### 4.12.7 Flash Option1 Register (Flash\_OPTR1)

**Address offset:** 0x20

**Reset value:** 0x0000 XXXX.

After the power-on reset (POR/OBL\_LAUNCH) is released, the corresponding value is read from the option byte area of the flash information memory and written to the corresponding option bit of the register.

| 31: 9 | Reserved | -   | -           | -                                        |
| 8: 0  | PCROP1SR | RW  |             | BANK1 PCROP zone start address (in Page) |

Notes:

- This register is set to 0x1FF without using the PCROP function
- Using the PCROP function:
  - For 128K products, this register is set to the start address +0x80;
  - For 256K products, this register is set to the start address +0x100;

For 384K products, this register is set to the start address +0x180, and can only protect the first 64KB of BANK1.

For 512K products, this register is set to the start address.

#### 4.12.13 Flash PCROP1 end address register (FLASH\_PCROP1ER)

**Address offset:** 0x3C

**Reset value:** 0x0000 0XXX.

After the power-on reset (POR/OBL\_LAUNCH) is released, the corresponding value is read from the option byte area of the flash information memory and written to the corresponding option bit of the register.

|      |      |      |      |      |      |      |                 |      |      |      |      |      |      |      |      |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8               | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | PCROP1ER [8: 0] |      |      |      |      |      |      |      |      |
| -    |      |      |      |      |      |      |                 | RW   | RW   | RW   | RW   | RW   | RW   | RW   | RW   |

| Bit   | Name     | R/W | Reset Value | Function                               |
|-------|----------|-----|-------------|----------------------------------------|
| 31: 9 | Reserved | -   | -           | -                                      |
| 8: 0  | PCROP1ER | RW  |             | BANK1 PCROP Zone End Address (in Page) |

Notes:

1. This register is set to 0x1FF without using the PCROP function
2. Using the PCROP function:

For 128K products, this register is set to the start address +0x80;

For 256K products, this register is set to the start address +0x100;

For 384K products, this register is set to the start address +0x180, and can only protect the first 64KB of BANK1.

For 512K products, this register is set to the start address.

## 5. Power Control (PWR)

### 5.1 Introduction

The PWR module performs the following functions:

- Chip power-on and power-off process control
- Analog PMU control signal generation
- Generation of memory low power control signal
- Low Power Mode Entry and Wake Timing Control
- PVD functionality

### 5.2 Power Structure

- The chip operating voltage is 2.3 to 3.6 V
- All low-power entry and exit logic is implemented in the VCCD power domain.
- The VBKP domain logic has an independent power-on reset BPOR
- The power-on reset of digital logic in the VDDD domain is generated by the VCCD module
- Using the VCC domain clock generated by HSI 16 as the clock for the standby mode entry and wake-up logic, HSI\_ON needs to be a VCCD domain signal
- In standby mode, IWDG can be configured to enable operation, and its counting clock is LSI, so the LSI clock needs to be output in standby mode, that is, the LSI clock will also output the VCCD domain clock.

## 5.2.1 System Main Power Supply

### 5.2.1.1 Independent A/D converter power supply and reference voltage

To improve conversion accuracy, the ADC is equipped with an independent power supply that can individually filter and mask the noise on the PCB.

- The ADC voltage source is input from a separate VCCA pin.
- The VSSA pin provides a separate power ground connection.

To improve the accuracy of the low-voltage input, users can connect a separate ADC external reference voltage input on the VREF+. The voltage on VREF + ranges from 2.3 V to VCCA.

### 5.2.1.2 Backup battery domain

To preserve the contents of the RTC backup register and power the RTC after the VCCD is powered down, you can connect the VBAT pin to a battery or other backup power source.

In order for the RTC to operate even after the main digital power supply (VCCD) is turned off, the VBAT pin needs to power each of the following modules:

- RCC BDCR Register
- RTC module (except RTC\_CR register)
- LSE Oscillator
- BKP registers
- PC13 to PC15 I/O

The switch of the VBAT power supply is controlled by a power-down reset circuit (BPOR) built into the reset module.

**Note:**

- After tRSTTEMPO (VCC start time) or PDR is detected, the power switch between VBAT and VCCD is still connected to VBAT.
- During the start-up phase, if the established VCCD is less than tRSTTEMPO (see tRSTTEMPO value in the datasheet) and  $VCCD > VBAT + 0.6\text{ V}$ , current can be injected into the VBAT by connecting an internal diode between the VCCD and the power switch (VBAT).

If the power supply/battery connected to the VBAT pin cannot support this current injection, it is highly recommended to connect a diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect the VBAT pin to the VCCD, which needs to be connected in parallel with a 100 nF decoupling ceramic capacitor.

When powering the backup domain via the VCCD (analog switch connected to the VCCD):

- PC14 and PC15 can be used as GPIO or LSE pins
- The PC13 can be used as a GPIO or configured for other functions (TAMPER pin, RTC calibration clock, RTC alarm, or second output)

Note: Due to the limited sink capability of this switch (3 mA), the following limitations exist when using GPIO PC13 through PC15 in output mode: the rate must not exceed 2 MHz, the maximum load is 30 pF, and these I/Os cannot be used as current sources (e.g., for driving LEDs).

When powering the backup domain via VBAT (the internal power switch is connected to VBAT because there is no VCCD), the following pins can be implemented:

- PC14 and PC15 can only be used as LSE pins

- PC13 can be used as an RTC additional function pin (TAMPER pin, RTC alarm clock or second output)

#### Backup domain access

After reset, the backup domains (RTC registers and RTC backup registers) will be protected against unintended write access. To enable access to the backup domain (RTC and RTC backup registers), you need to configure as follows:

- Enable the power interface clock by PWREN position 1 in the RCC\_APB1ENR1 register
- Enable access to the backup domain by DBP location 1 in the PWR\_CR1 register
- Configure the RTCSEL register in the RCC backup domain control register (RCC\_BDCR) to select the RTC clock source
- Configure RTCEN in RCC Backup Domain Control Register (RCC\_BDCR) to enable RTC clock

### 5.2.1.3 VDDD voltage regulator

Embedded linear VR powers all digital circuitry other than the backup domain and standby (wake-up) circuitry.

When activated by software, the voltage regulator is always enabled after reset. Depending on the application mode, three different modes can be used to work:

- In Run mode, the voltage regulator provides full power to the core, memory and digital peripherals. In this mode, the regulator output voltage can be adjusted by software to different voltage values (configurable via the VOS [1: 0] bit of the PWR\_CR register).
- In stop mode, the main regulator or low power regulator supplies a low power voltage to the VDDD domain, saving the contents of the registers and internal SRAM. The regulator may also be placed in main regulator mode (MR) or low power mode (LPR).
- In standby mode, the voltage regulator powers down. Except for the standby (wake-up) circuit and backup domain, the contents of the registers, SRAM1 and CCM SRAM will be lost, and the contents of SRAM2 can be optionally preserved (controlled by the RRS bit of PWR\_CR3).

## 5.2.2 Power Detection

### 5.2.2.1 POR/PDR

The chip contains Power-on reset (POR) and Power-off reset (PDR) modules to provide power-related resets. Where POR/PDR works by default in all power modes. POR/PDR output reset low active.

### 5.2.2.2 PVD

The PVD module detects whether the VCC is lower than the threshold set by PWR\_CR2. PLS.

The PVD function is enabled by configuring the PWR\_CR2. PVDE register.

The PVDO flag in the Power Control/Status Register (PWR\_CSR) is used to indicate whether VCC is above or below the voltage threshold of PVD. This event is internally connected to Line16 of EXTI and generates an interrupt if the interrupt is enabled in the external interrupt register. A PVD interrupt occurs when the VCC falls below the PVD threshold or when the VCC falls above the PVD threshold, according to the rising/falling edge trigger setting of EXTI Line16. In practical applications, this feature can be used to perform emergency shutdown tasks.

## 5.3 System Low Power Mode

By default, the microcontroller is in Run mode after a system or a power Reset. In the running mode, the CPU provides clock through the HCLK and executes program code. The system provides multiple low-power modes to save power when the CPU is not required to run, such as when waiting for external events. It is up to the user to select the specific low-power mode according to the application, and seek the best balance between low power consumption, short startup time and available wake-up sources.

The device has five low-power modes:

- Sleep mode: The kernel stops running, and the kernel peripherals (NVIC, Sys Tick) can be configured to run;
- Low-power run mode (Low-power run): the system clock is configured to HSI16 and HCLK is divided below 8 (i.e. HCLK is not greater than 2MHz), and VDDD is powered by LPR;
- Low-power Sleep mode (Low-power Sleep): enter the Sleep mode from Low-power run;
- Stop mode: All high-speed clocks in the VDDD domain are turned off, and SRAM and register contents are held. The LSI and LSE can be selected whether to turn on or not according to the wake-up source. The LDO working mode when entering STOP can be configured, and both MR and LPR configurations are supported. The power consumption of these two modes decreases in turn, and the wake-up time becomes longer in turn.
- Standby mode: The VDDD domain is powered off and only the VCCD and VBKP domains work. You can select whether SRAM2 is maintained by configuring (PWR\_CR3. RRS); The LSI and LSE can be selected whether to turn on or not according to the wake-up source.

The device has VBAT power supply, so when the VCC is powered down, the device only works in the VBKP domain.

In addition, the power consumption of the operating mode can be reduced by one of the following methods:

- Slowing down system clocks
- When APBx and AHBx peripherals are not in use, the corresponding peripheral clock is turned off.

Figure 5-1 Low power mode state transition diagram

Table 5-1 Low power modes

| Mode                     | Clock status                                                | Entry conditions                                                                  | Exit Condi-<br>tions                                      | Wake-up de-<br>lay        | System clock<br>after wake up | MR<br>sta-<br>tus | LPR<br>sta-<br>tus |

1. The system clock is the sys\_clk (reference RCC module) cycle configured before entering SLEEP.
2. The MR stabilization time is about 2  $\mu$ s;
3. Including HSI16 stabilization time and memory (Flash) low power exit stabilization time;
4. There are two configurations, HSI16 and MR are turned on simultaneously (5.5  $\mu$ s) and HSI16 waiting for MR to stabilize before turning on (7.5  $\mu$ s).

5. Including MR start-up to stabilization time of 10 $\mu$ s, HSI16 stabilization time of 2 $\mu$ s, Flash stabilization time of 5.1  $\mu$ s and power-on internal calibration data loading time of 20 $\mu$ s.

The above are all simulation values, and the actual value is estimated to be less than the above time (please refer to the data sheet for specific parameters)

The following table shows whether each functional module exists in different modes:

| Peripheral                      | Run | Sleep | LP Run | LP Sleep | Stop |         | Standby |         | VBAT |

Notes:

1. Y = YES (ENABLE); O = Optional (Off by default, can be enabled by software); -= not available
2. FlashInSleepand LP \_Sleepmodes, the software can select whether the clock is on or not
3. SRAM InSleepand LP \_Sleepmodes, the software can select whether the clock is on or not
4. The SRAM2 may be maintained
5. In Stop mode, the HSI 16 can be switched by software
6. LPUART can be received in Stop mode, resulting in START and address matching interrupt wake-up
7. I2C provides address matching and timeout interrupt wake-up in Stop mode
8. In Standby mode, IO can be configured as pull-up, pull-down or float
9. IO with wake-up function in Standby mode: PA0 PA2 PC5 PC13 PE6

### 5.3.1 Normal Operating Mode

In normal operation mode, power consumption can be reduced by reducing the system clock (SYSCLK, HCLK, PCLK); Before entering SLEEP mode, the peripheral clock frequency can also be reduced by frequency division;

In the normal operation mode, different peripherals and memories can separately turn off the clock through gating to reduce power consumption; Before entering SLEEP, peripheral clocks that are not used for wakeup can be turned off;

### 5.3.2 Low power operating mode

To further reduce the power consumption in the operating mode, the MR can be turned off, and the VDDD domain is powered by the LPR. At the same time, reduce the operating frequency of the system, which cannot exceed 2 MHz;

#### IO status in low power operation mode

In the low-power operation mode, all IO states remain consistent with the operating state.

#### Entry of low power operating mode

1. Optional: The program jumps to SRAM to run, and configures Flash to enter low power mode;
2. Reduce the system clock to less than 2 MHz;
3. Set VDDD to use LPR power and MR to turn off.

#### Exit of low power operating mode

1. Set VDDD to use MR power;
2. Wait for the MR power-on to complete;
3. Restore the normal system clock.

| Low-power run | Description                                                           |
|---------------|-----------------------------------------------------------------------|

### 5.3.3 Low power mode entry and exit

#### Enter:

Low power mode can be entered by executing a WFI (Wait for Interrupt) or WFE (Wait for Event) instruction, or by SLEEPONEXIT position 1 in the system control register upon return from ISR.

Only when there is no interrupt or event pending, you can enter low power mode through WFI or WFE, that is, the CPU needs to clear the suspended interrupt or event before entering low power.

In the process of entering the low power mode, a wake-up signal appears, and the system will judge how to deal with it according to the current state:

1. Exit into the flow to handle wakeup interrupts or events before the system clock shuts down;
2. After the system clock is turned off, hold the wake-up signal first, and then enter the low-power mode normally. After entering the low-power mode, wake up according to the normal wake-up process.

#### Exit:

Exit these two low-power modes depending on how you enter sleep and stop modes:

- Any peripheral interrupts acknowledged by NVIC can wake up the device if you enter low power mode using a WFI command or return from the ISR.
- If the WFE instruction is used to enter the low power mode, the MCU will immediately exit the low power mode when an event occurs. The wakeup event can be generated either by:

— NVIC IRQ Interrupt:

When SEVONPEND = 0, you can wake up from the WFE by enabling the interrupt enable control bit of the NVIC and the corresponding peripheral. When the system wakes up, the interrupt suspend bits in NVIC and peripherals must be cleared;

When SEVONPEND = 1, you can wake up from WFE only by enabling the interrupt enable control bit of the peripheral, and the interrupt enable in NVIC can select whether it is enabled or not. When the system wakes up, the interrupt suspend bit in the peripheral must be cleared. If the interrupt in NVIC is enabled, it must also be cleared at the same time;

All NVIC interrupts can wake up the CPU, even those not enabled in NVIC.

— Event:

Configure an external or internal EXTI line to event mode. When the CPU recovers from the WFE, it is not necessary to clear the interrupt suspend bit or the NVIC IRQ channel suspend bit of the EXTI peripheral because the suspend bit of the corresponding event line is not set to 1. Interrupt flags in peripherals may need to be cleared. This mode takes the shortest time to wake up because no time is spent on the entry or exit of the interrupt.

When an external reset (NRST pin), an IWDG reset occurs, a rising edge appears on the enabled WKUPx pin, or an RTC wake-up event is triggered, the MCU exits standby low power mode.

After waking up from standby mode, the program will be re-executed in the manner after reset (starting boot pin sampling, reset vector acquisition, etc.).

#### 5.3.4 Sleep Mode

Before entering sleep mode, all interrupt pending bits must be cleared.

##### IO status in sleep mode

In sleep mode, all IO states remain consistent with the running state.

| Sleep Mode    | Description                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 | The low power sleep mode can only be accessed from the low power operating mode<br>Returns from the lowest priority ISR, and:<br>--SLEEPDEEP = 0 and<br>--There is no interrupt hanging.                                                                                                                    |
| Mode Exit       | Enter using WFI or returning from lowest priority ISR: Interrupt (enabled)<br>Entered with WFE and SEVONPEN = 0: Wake event<br>Enter with WFE and SEVONPEN = 1: Peripheral enable interrupt (even if disabled in NVIC)<br>Exit the low power sleep mode and the system enters the low power operation mode. |
| Wake-up delay   | None                                                                                                                                                                                                                                                                                                        |

#### 5.3.6 Stop mode

The stop mode is based on kernel SleepDeep mode and peripheral clock gating. The VDDD domain LDO can be configured in either normal mode (MR) or low power mode (LPR). In the stop mode, all high-frequency clocks in the VDDD domain will stop, and the stopped clocks include PLL, HSI16, HSI48 and HSE, where PLL, HSI48 and HSE are turned off by software control, and HSI16 is turned off by hardware. The internal SRAM and register contents will be preserved.

##### IO status in stop mode

In stop mode, all IO states remain consistent with the running state.

##### Entry of stop mode

If FLASH programming is being executed, the entry of stop mode will be delayed until the end of the memory access (controlled by the HREADY signal of the FLASH controller interface and the operation flag, and the software can execute WFI or WFE instructions after the end).

Before entering the stop mode, if the APB domain is being accessed, the entry of the stop mode will be delayed until the end of the APB access. (via Software Assurance)

In stop mode, the following functions can be selected by programming each control bit:

- Independent Watchdog (IWDG): The IWDG is booted by writing to its key register or using a hardware option. Once started, it cannot be stopped except upon a reset.
- Real Time Clock (RTC): Configured via the RTCEN bit in the RCC backup domain control register (RCC\_BDCR).
- Internal RC Oscillator (LSI RC): Configured by RCC clock control and LSION bit in the status register (RCC\_CSR).
- External 32.768kHz oscillator(LSE OSC): Configured via the LSEON bit in the RCC backup domain control register (RCC\_BDCR).

In Stop mode, some low-power peripherals can also be configured as wake-up sources, such as LPUART and I2C;

Before entering stop mode, some analog modules (ADC, DAC) can also work. In order to further reduce power consumption, please turn off before entering.

#### Exit of Stop Mode

Exiting stop mode, HSI16 will be selected as the system clock. If you are configured to exit the stop mode and enter the low power operation mode, you need to configure the system clock below 2 MHz before entering the stop mode; At the same time, select the power supply mode MR (STOP0) or LPR (STOP1) of VDDD.

When entering Stop, the required delay after startup is different according to the configured VDDD power supply mode.

| Stop mode     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

#### 5.3.7 Standby mode

In standby mode, VR (including MR and LPR) stops working, and the VDDD domain is powered off. PLL, HSI 16, HSI 48, HSE are all closed, with PLL, HSI 48, and HSE being closed by software control, and HSI 16 being closed by hardware. Except for the registers of the VBKP domain (RTC register and backup register) and standby circuit, other SRAM1 and CCM SRAM and register contents are lost. Depending on the configuration SRAM2, you can choose whether to be powered by the LPR alone.

#### IO status in standby mode

In standby mode, IO can be configured as pull-up and pull-down, or analog mode;

The output port PC13 of the RTC, the two ports PC14 and PC15 of the LSE, the WKUP IO and the TAMPER IO are all in the working state;

### Entry of standby mode

In Standby mode, the following features can be selected by programming individual control bits:

- Independent Watchdog (IWDG): The IWDG is booted by writing to its key register or using a hardware option. Once started, it cannot be stopped except upon a reset.
- Real Time Clock (RTC): Configured via the RTCEN bit in the RCC backup domain control register (RCC\_BDCR).
- Internal RC Oscillator (LSI RC): Configured by RCC clock control and LSION bit in the status register (RCC\_CSR).
- External 32.768kHz oscillator(LSE OSC): Configured via the LSEON bit in the RCC backup domain control register (RCC\_BDCR).

| Standby mode   | Description                                                                                                                                                                                                                                                                       |

|                | IWDG reset                                                                                                                                                                                                                                                                        |
| Wakeup latency | HSI16 wake-up time + LDO power-on time + LDO waiting time (configurable 0us/5us/10us/20us) + FLASH waiting time 3us (may coincide according to the configuration time) + internal calibration value load time                                                                     |

In standby mode, except for the following parts, the remaining IOs are in a high impedance state:

- Reset pin
- TAMPER pin when set to anti-intrusion or calibration output
- 5 WKUP pins (PA0/PC13/PE6/PA2/PC5) if enabled

### 5.3.8 Debugging of stop mode and standby mode

In stop and standby modes, by default, the debugging function will be interrupted because the CPU core is clockless. However, if the relevant register in DBGMCU\_CR are configured, debugging can still be performed even if the CPU enters SLEEPDEEP mode.

### 5.3.9 Automatic wake-up in low power mode (AWU)

The RTC can wake up the MCU in the low power mode without relying on an external interrupt (automatic wake-up mode). The RTC provides a programmable time base for periodically waking up from stop or standby modes. By programming the RTCSEL [1: 0] bit of the backup area control register (RCC\_BDCR), two of the three RTC clock sources can be selected to implement this function:

- Low power 32.768 kHz external crystal oscillator (LSE)

The clock source provides a low-power and accurate time reference. (consumes less than 1  $\mu$  A under typical conditions)

- Low power internal RC oscillator (LSI)

Using this clock source, the cost of a 32.768 kHz crystal oscillator is saved. But that RC oscillator will increase power consumption slightly. In order to wake the system from stop mode with an RTC alarm event, you must do the following:

- Configure EXTI17 as rising edge trigger.
- Configure the RTC so that it can generate wake-up events.

If you want to wake up from standby mode, you do not have to configure EXTI17 (wake up standby directly with the RTC alarm wake event).

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

## 5.4 TIMx registers

These peripheral registers can be operated in a half-word (16-bit) or word (32-bit) manner.

### 5.4.1 Power Control Register 1 (PWR\_CR1) (0x00)

## 6. Reset and Clock Control (RCC)

### 6.1 Introduction

#### 6.1.1 Main Features

This module completes the following functions:

- Generate system clock and system reset
- Generate individual module clock and reset
- Generate a clock source control signal

### 6.2 System reset

System reset resets all registers to reset values except the reset flag in the clock control register CSR and the registers in the backup domain.

System reset is generated when one of the following events occurs:

- NRST pin low (external reset)
- Window Watchdog Count End (WWDG Reset)
- End of Independent Watchdog Count (IWDG Reset)
- Software Reset (SYSRESETREQ Reset)
- Low Power Management Reset (NRST\_STDBY/NRST\_STOP)
- Option Byte Load Reset

#### 6.2.1 NRST pin (external reset)

With a specific option bit (NRST\_MODE), the NRST pin can be configured to:

- Reset Inputs/Outputs (default when device is delivered)

Any valid reset signal on the reset input/output (default when device is delivered) pin is propagated to device internal logic, and all internal reset sources are driven to this pin via a pulse generator. The GPIO function (PF5) is not available. The pulse generator guarantees a minimum reset pulse duration of 20  $\mu$ s for each internal reset source output on the NRST pin. This mode is always active (independent of the option byte setting) during each device power-on reset (until the option byte is loaded).

- Reset input

In this mode, any valid reset signal on the NRST pin is propagated to the internal logic of the device, the reset generated inside the device. In this configuration, the GPIO function (PF5) is not available.

- GPIO

In this mode, the pin can be used as a PF5 standard GPIO. The reset function of the pin is not available. The reset can only be done from the device internal reset source and does not propagate to this pin.

#### 6.2.2 Software reset

This can be determined by looking at the reset flag in the RCC clock control and status register (RCC\_CSR). To software reset the device, you must interrupt and reset the SYSRESETREQ position 1 in the CPU control register.

#### 6.2.3 Low Power Management Reset

There are two ways to trigger a low-power management reset:

- Reset occurs when entering standby mode:

This reset is enabled by clearing the nRST\_STDBY bit in the user option byte. And the PWR\_CR.PDDS register is configured to standby mode. When entering the low power mode, the device will reset instead of entering the standby mode.

- Reset is generated when entering stop mode:

This reset is enabled by clearing the nRST\_STOP bit in the user option byte. And the PWR\_CR.PDDS register is configured to stop mode. When entering the low power mode, the device will reset instead of entering the stop mode.

#### 6.2.4 Option Byte Load Reset

When the OBL\_LAUNCH bit (bit 27) is set in the FLASH\_CR register, an option byte load reset is generated. This bit is used to load via the software boot option byte.

### 6.3 Power reset

A power reset is generated when one of the following events occurs:

- Power On/Power Off Reset (POR/PDR Reset)
- Exiting Standby mode

A power reset resets all registers except the backup domain.

The reset entry vector is fixed at address 0x0000\_0004 in the memory map.

### 6.4 Backup domain reset

A backup domain reset will reset all backup domain registers, including RCC\_BDCR, backup registers, and RTC partial registers.

A backup domain reset is generated when one of the following events occurs:

- Software reset, triggered by setting the BDRST bit in the RTC domain control register (RCC\_BDCR).
- VCC or VBAT power on, if both supplies have previously been powered off.

### 6.5 Uniform handling of resets other than backup domain resets

Except for the backup domain reset, in the NRST pin reset input/output mode, other source resets act on the NRST pin, which keeps the clock low during the reset process.

The circuit is shown in the figure below:

When the system is internally reset (high level is active), the pulse generator starts to generate a pulse signal and ensures that the pulse signal lasts for at least 20μs. This pulse signal turns on the N-tube. When the N tube is turned on, the voltage of the NRST pin will be continuously pulled down. When it

is pulled down to VIL, the NRST pin will generate a low-level signal. After the signal is Schmidt triggered and filtered, a system reset is generated (low active).

Note 1: Reset sources other than the external PIN reset source, that is, the source of the pulse generator, will not produce system reset after 30 us filtering;

Note 2: After the reset source of the pulse generator generates a system reset, in addition to its own reset flag, the external pin reset flag will also be set.

## 6.6 Clock structure

The clock structure is shown in the following figure:

## 6.7 Clock sources

The following clock sources exist in the system:

### 6.7.1 HSE clock

External High Frequency OSC. Frequency Range 4 to 32 MHz.

The settling time of the HSE clock is counted by the analog HSE module, which generates the HSE\_RDY signal after starting and settling.

The HSE clock can have two operating modes:

- External XTAL OSC + internal start circuit (HSEBYP = 0)
- External clock input via OSC\_IN IO (HSEBYP = 1)

In order to ensure that the first CLOCK output by CLOCK is a stable CLOCK, HSE contains a counter inside, and the rising edge of the first CLOCK is output after the counting is completed. The counting period at HSEBYP = 1 is half that of HSEBYP = 0.

### 6.7.2 HSI16 clock

Internal 16 MHz RC oscillator. Compared with HSE, it has low power consumption, short stabilization time, but low accuracy. The analog HSI module generates an HSI\_RDY signal after starting and stabilizing.

After the power-on reset, during the load phase, the calibration value of the HSI is loaded into the RCC\_CR.HSICAL register.

After waking up from stop mode, the HSI will act as the system clock source.

### 6.7.3 HSI48 clock

The HSI48 clock supports self-calibration through the CTC module, and the HSI48 is used as the clock of the USB module.

### 6.7.4 PLL clock

The PLL module is used to double the frequency of HSI or HSE clocks. The PLL input clock frequency range is 2 ~ 32 MHz, and the output clock frequency range is 24 ~ 170 MHz.

The PLL lockout time is typically 25  $\mu$ s and the maximum is 100  $\mu$ s.

### 6.7.5 LSE clock

External 32.768 kHz OSC, used as a low power clock.

You can balance settling time and power consumption by configuring LSEDRV. The LSE stabilization time is 0.5 s (typical). The LSE stabilization signal is generated by the LSE analog module.

Similar to the HSE source, the LSE also has two sources:

- 32.768 kHz XTAL + internal start circuit (LSEBYP = 0)
- External clock via OSC32\_IN input (LSEBYP = 1)

In order to ensure that the first CLOCK output by CLOCK is a stable CLOCK, LSE contains a counter inside, and the rising edge of the first CLOCK is output after the counting is completed. The counting period at LSEBYP = 1 is half that of LSEBYP = 0.

In the case of LSEBYP = 1, the clock output by the MCO is the original embedded clock and is not controlled by the LSE\_ON signal. However, the logic using the LSE clock is controlled by the LSE\_ON signal.

### 6.7.6 LSI clock

Internal low frequency 40 kHz clock. Used as an IWDG, RTC clock.

### 6.7.7 HSI10M clock

This clock acts as a low precision clock and serves as a filtered count for the NRST pin. Every time a system reset is generated, after passing through the pulse generator, it is returned through the NRST pin, so the HSI10M clock is enabled every time a reset is generated.

## 6.8 Clock security system (CSS)

The clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay and disabled when this oscillator is stopped.

If a fault is detected on the HSE clock, the HSE oscillator is automatically disabled and the clock fault event is sent to the interrupt input of the timers (TIM1/TIM8 and TIM15/16/17) and an interrupt is generated to notify the software of the fault (Clock Safe System Interrupt CSSI), allowing the MCU to perform rescue operations. CSSI is linked to Cortex via an FPU NMI (unmaskable interrupt) exception vector® -M4F.

Note: Once CSS is enabled, if the HSE clock fails, a CSS interrupt occurs and an NMI is automatically generated. NMI executes indefinitely unless the CSS interrupt suspend bit is cleared. Therefore, in the NMI ISR, the user must clear the CSS interrupt by setting the CSSC bit in the clock interrupt register (RCC\_CIR

If the HSE oscillator is used directly or indirectly as the system clock (indirectly meaning: it is used as the PLL input clock and the PLL clock is used as the system clock), the detected failure causes the system clock to switch to the HSI16 oscillator and disables the HSE oscillator. If the HSE clock is the clock source of the PLL used as the system clock, the PLL is also disabled.

## 6.9 Peripheral clock enable register

Each peripheral clock may be enabled by the xxxxEN bit of the RCC\_AHBxENR, RCC\_APBxENRy register.

When the peripheral clock is not active, read or write access to peripheral registers is not supported.

The enable bit has a synchronization mechanism, after the enable bit is set, there is a delay of 2 clock cycles before the clock is activated.

Note: After enabling the clock for the peripheral device, the software must wait some time before accessing the peripheral registers.

## 6.10 TIMx registers

This module register can be accessed by bytes (8 bits) [except RCC\_BDCR], half-words (16 bits), or words (32 bits).

### 6.10.1 Clock control register (RCC\_CR)

### 6.10.2 Clock configuration register (RCC\_CFGR)

Address offset: 0x04

Reset value: 0x0000\_0000

When the clock source is switched, there is a waiting period of 1 or 2 clocks to access this register.

When the APB or AHB frequency division value is updated, there may be a waiting period of 0 to 15 clocks to access this register.

#### 6.10.4 AHB1 peripheral reset register (RCC\_AHB1RSTR)

Address offset: 0x28

Reset value: 0x0000\_0000

The register is set and cleared by software. After the software is set, the module maintains a reset until the software clears.

#### 6.10.6 APB1 peripheral reset register 1 (RCC\_APB1RSTR1)

Address offset: 0x38

Reset value: 0x0000\_0000

The register is set and cleared by software. After the software is set, the module maintains a reset until the software clears.

#### 6.10.15 RTC domain control register (RCC\_BDCR)

Address offset: 0x70

Reset value: 0x0000\_0000

The LSEON, LSEBYP, LSEDRV, RTCSEL and RTCEN bits in the register are in the backup domain and can be reset only when the backup domain is reset, and the backup domain reset includes a backup domain power-on reset (BPOR) and a backup domain soft reset (BDRST).

When this register is accessed continuously,  $0 \leq \text{wait state} \leq 3$ .

This register does not belong to the VDDD domain but belongs to the RTC domain (VBAK domain).

After reset, the register needs to be write-protected, that is, the PWR\_CR1.DBP bit needs to be set to 1.

#### 6.10.16 RCC control/status register (RCC\_CSR)

Address offset: 0x74

Reset value: 0x0800\_0000

The reset flag bit in this register can only be reset by power reset, and the rest by system reset.

When this register is accessed continuously ,  $0 \leq \text{wait state} \leq 3$ .

## 7. Backup register (BKP)

### 7.1 Introduction

The backup register consists of 32 32-bit registers, which can be used to store 128 bytes of user data. The modules are in the backup domain, and when the VCC power is cut off, they are still maintained by VBAT (Backup Domain Power). They are also not erased when the system is awakened in standby mode, system reset or power reset (POR).

The backup register is reset by a backup domain power-on reset (BPOR) or software reset (BDRST), and when an intrusion event is detected, the contents of the backup register are erased.

The BKP control register is used to manage intrusion detection and RTC calibration functions.

After reset, the backup registers and RTC are not accessible, and the backup domain is protected from possible unexpected write operations. Do the following to enable write access to the backup registers and RTC:

- Turn on the power and back up the domain module clock by setting the PWREN and BKPEN bits of register RCC\_APB1ENR1
- The DBP bit of the power supply control register 1 (PWR\_CR1) is set to 1 to enable write access to the backup register and the RTC.

### 7.2 Main features

- Supports 128-byte data backup register
- Status and control registers that manage intrusion detection and have interrupt functions
- Store RTC Check Value

- Output an RTC calibration clock, an RTC alarm pulse or a second pulse on the PC13 pin (when this pin is not used for intrusion detection)
- Backup registers are protected by RDP (Read Protection) of FLASH

## 7.3 Functional description

### 7.3.1 Intrusion detection

When the signal on the TAMPER pin changes from 0 to 1 or from 1 to 0 (depending on the TPAL bit of the backup control register BKP\_CR), an intrusion detection event occurs. The intrusion detection event clears all data backup register contents. However, in order to avoid loss of intrusion events, the intrusion detection signal is a logical AND of the signal of the edge detection and the intrusion detection permission bit, so that intrusion events that occur before the intrusion detection pin is permitted can also be detected.

- When TPAL = 0: If the pin is already high before starting the intrusion detection TAMPER pin (by setting the TPE bit), once the intrusion detection function is started, an additional intrusion event will be generated (although there is no rising edge after the TPE position '1').
- When TPAL = 1: If the intrusion detection pin TAMPER is already low before the intrusion detection pin is started (by setting the TPE bit), once the intrusion detection function is started, an additional intrusion event will be generated (although there is no falling edge after the TPE position '1').

Set the TPIE bit of the BKP\_CSR register to '1' to generate an interrupt when an intrusion event is detected. After an intrusion event is detected and cleared, the intrusion detection pin TAMPER should be disabled. Then, the intrusion detection function is reactivated with the TPE bit before writing to the backup data register again. In this way, the software can be prevented from writing to the backup data register when there is still an intrusion event on the intrusion detection pin. This is equivalent to level detection of the intrusion pin TAMPER.

NOTE: The intrusion detection function is still active when the VCC power is disconnected. To avoid unnecessarily resetting the data backup registers, the TAMPER pin should be connected to the correct level off-chip.

### 7.3.2 RTC calibration

For the convenience of measurement, the RTC clock can be output to the intrusion detection pin TAMPER by 64 division. This function is turned on by setting the CCO bit of the RTC check register (BKP\_RTCCR).

By configuring the CAL [6: 0] bit, the clock can be slowed down by up to 121 ppm.

#### 7.3.2.1 Overview

Real-time clock (RTC) accuracy is a requirement for most embedded applications, but due to changes in external ambient temperature, the crystal frequency of the clock causes the RTC accuracy to be not as accurate as expected. The circuit is calibrated using a digital clock, allowing the application to compensate for crystal and temperature changes.

#### 7.3.2.2 RTC calibration method

The RTC clock can be driven by a quartz crystal controlled oscillator with a rated frequency of 32.768 kHz. The crystal oscillator is one of the most accurate circuits to provide a fixed frequency. There are two reasons for clock errors:

1. Temperature Change
2. Crystal changes

As mentioned earlier, most clock chips compensate for crystal frequency and temperature changes by using cumbersome trimmer capacitors. The design employs periodic counter correction. The digital calibration circuit eliminates 0 to 127 cycles every 220 clock cycles. The number of pulses blanked depends on the value of the RTC clock calibration register BKP\_RTCCR.CAL loaded into the BKP. Since the RTC clock calibration register is in the backup domain, if the battery is connected to the VBAT pin, the calibration value is not lost even if the device is powered off.

The structure block diagram looks like this:

Note: The clock output on the pin is the RTC clock before calibration, so the calibration does not change its value.

The effect of each calibration step is to subtract 1 oscillator cycle for every 1 048 576 (220) actual oscillator cycles. That is, the adjustment amount of each calibration step in the calibration register is 0.954 (1000000/220) ppm. As a result, the oscillator clock can be slowed down from 0 to 121 ppm.

The table below shows the number of ppm and seconds each bit is represented in real time in each month (30 days).

| Calibration value | Rounded to nearest ppm | Values are in seconds, rounded to the nearest second per month (30 days) | Calibration value | Rounded to nearest ppm | Values are in seconds, rounded to the nearest second per month (30 days) |
|-------------------|------------------------|--------------------------------------------------------------------------|-------------------|------------------------|--------------------------------------------------------------------------|

As mentioned above, the RTC clock calibration circuit only subtracts cycles from the crystal clock. Based on the RTC prescaler value set to 32768 by default, faster crystal frequencies ( $> 32.768$  kHz) can be calibrated, while slower crystal frequencies ( $< 32.768$  kHz) cannot be compensated (only the faster crystals are calibrated, the slower ones will exacerbate the slower situation). So only the crystal frequency range [32 772, 32 768] can be calibrated.

Since the crystal frequency may vary around 32.768 kHz, the crystal frequency may be adjusted from 32.768 kHz to 32.766 kHz, for example, by setting the RTC prescalation to 32766 (instead of 32768).

In this way, the range of crystal frequencies of [32770, 32766] can be compensated for.

### 7.3.2.3 Calculate the amount of calibration required

In order to determine how much calibration is needed in a given application, it is necessary to use the output function of the RTC clock on a case-by-case basis. The RTC clock output can be used to

measure the accuracy of the crystal oscillator. If the frequency of the crystal oscillator is an exact 32.768 kHz, the frequency of the RTC clock output is exactly 512 Hz.

The method can be divided into the following steps:

1. Enable the Low Speed External Oscillator (LSE), select LSE as the RTC clock source, and then enable the RTC clock.
2. Output the 64-point frequency of the RTC clock on the RTC\_OUT pin (PC13) for crystal frequency measurement. This is achieved by placing CCO position 1 in BKP\_RTCCR.
3. Calculate crystal frequency deviation (ppm). Assuming the RTC prescaler value of 32766, the deviation in ppm can be quickly calculated by dividing the measured deviation of 511.968 Hz ( $32766/64 \approx 511.968$ ) by 511.968 and multiplying the result by 1 million. This table is a direct look-up table of calibration values based on variation values expressed in ppm.
4. Write calibration values to the RTC calibration register to compensate for crystal deviation.

Note: To set the RTC prescaler to 32766, write 32765 to the RTC prescaler register.

For example, if the frequency measured in the actual measurement is 511.982 Hz,  $\delta$  is 0.014. Divided by 511.968 and multiplied by 1 million, the result is 27.35 ppm. In this case, the closest compensation value is 28. The error will be reduced from 27.35 ppm (71 seconds per month) to 0.65 ppm (1.7 seconds per month).

Note: Since the principle of RTC calibration is to ignore part of the RTC clock pulse, it does not improve counting in short time, it only improves counting in long time. For example, using an RTC count of 0.01 seconds without calibration would be more accurate than with calibration. Since the calibration cycle may or may not occur within the time frame considered, the resulting values may vary significantly. Therefore, depending on the application, it is preferable not to use calibration.

### 7.3.3 Erasure of backup registers

The backup register may be erased in the following ways:

- ① VBAT domain power-on reset
- ② The intrusion detection circuit successfully captures the intrusion event
- ③ BDRST (backup domain soft reset) of register RCC\_BDCR is written to 1
- ④ RDP level Changes from 1 to 0
- ⑤ TEF flag bit is 1

Note: When erasing is being done, the bus will be in an unanswering state, and the bus cannot perform any read and write operations on the BKP.

## 7.4 TIMx registers

Note: All registers of the BKP module can only be accessed in word mode

## 8. CRC Computing Unit (CRC)

### 8.1 Introduction

The cyclic redundancy check (CRC) unit may calculate the CRC code from the 8-bit, 16-bit, 32-bit generator polynomial using a 7-bit, 8-bit, 16-bit, 32-bit custom generator polynomial.

In other applications, CRC-based techniques are used to verify the integrity of data transmission or storage. Within the field of functional safety standards, CRC-based technologies provide a way to verify the integrity of flash memory. The CRC computing unit may compute the identity of the software at the time of the program running, then compare it with the reference identity generated at the time of connection, and then store it in a designated memory space.

### 8.2 CRC main features

- Using CRC-32 Ethernet Polynomial:  $0x4C11DB7$

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

- Supports programmable polynomials, and the polynomial bit width is also programmable (supports 7, 8, 16, 32-bit polynomials)
- Supports calculation of 8, 16, 32 bits of data
- Customizable CRC initial value
- General purpose 32-bit register (can be used to store temporary data)
- With input cache function
- One 32-bit data register for input/output
- CRC calculation time: 4 AHB clock cycles (HCLK) required for 32-bit data; For 16-bit data, 2 AHB clock cycles are required; 1 AHB clock cycle (HCLK) required for 8-bit data
- Support input data inversion, output data inversion
- The CRC\_DR register can be accessed by the AHB bus at 8 bits right aligned, 16 bits right aligned, 32 bits, and other registers can only be accessed by the AHB bus at 32 bits

### 8.3 CRC functional description

#### 8.3.1 CRC Structure Block Diagram

Figure 8-1 Structure of CRC module

### 8.3.2 CRC Operation

The CRC computing unit contains one 32-bit data register (CRC\_DR). For write operations, it is used to save input data; For read operations, it is used to save the previous CRC calculation results. Each time the data register is written, the calculation result is a combination of the previous CRC calculation result and the new calculation result (CRC calculation is performed on the entire 32-bit word, rather than byte by byte), depending on the format of the written data. The CRC\_DR register can be accessed by words (32 bits), right-aligned half-words (16 bits), right-aligned bytes (8 bits), while other CRC registers only allow 32 bits.

For data with different bit widths, the CRC calculation module needs different time, as follows:

- Computing 32-bit data requires 4 AHB clock cycles
- Computing 16-bit data requires 2 AHB clock cycles
- It takes 1 AHB clock cycle to calculate 8-bit data

The input cache allows the user to write the second data immediately after the first data is written, without waiting for the previous data to be calculated.

Users can dynamically adjust the data size to reduce the number of accesses to this module when calculating a specific number of bytes of data. For example, to calculate a 5-byte data, one word of data can be written to this module, and then one byte of data can be written to obtain the calculation result.

This module supports input data inversion function to adapt to different size and size ends. According to REV\_IN [1: 0] of the CRC\_DR register, the input data inversion can be inverted in units of 8 bits, 16 bits, and 32 bits.

For example, for input data 0x1A2B3C4D that requires a CRC operation:

- The data after inversion in bytes (8 bits) is 0x58D43CB2
- The data after inversion in units of half words (16 bits) is 0xD458B23C
- The data after inversion in words (32 bits) is 0xB23CD458

The REV\_OUT bit in the CRC\_CR register can invert the output data. This operation is done at the bit level, for example: the output data is 0x112233544, which is inverted to become 0x22CC4488

Placing the RESET position 1 of the CRC\_CR register enables the initial value of the CRC calculator to be loaded with a programmable value (default value is 0xFFFFFFFF)

The CRC initial value can be programmed to the value contained in the CRC\_INIT register. When the CRC\_INIT register is written, the CRC\_DR register is automatically initialized.

The CRC\_IDR register may be used to hold temporary values related to the CRC calculation. It is not affected by the RESET bit in the CRC\_CR register.

### 8.3.3 Polynomial programmability

The coefficients of the polynomial can be fully customized by the CRC\_POL register, and the bit width of the polynomial can be configured as 7 bits, 8 bits, 16 bits, 32 bits according to POLYSIZE [1: 0] of the CRC\_CR register. Even polynomials are not supported, for example: even polynomials are of the form  $x+x^2 + \dots + x^n$ , while odd polynomials are of the form  $1 + x+x^2 + \dots + x^n$ .

If the CRC data is less than 32 bits, the value of CRC will be read from the least significant bit of CRC\_DR.

In order to obtain a reliable CRC calculation result, the value or size of the polynomial cannot be changed during the calculation of the CRC. The CRC must be reset before the CRC polynomial can be changed.

The default polynomial is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

## 8.4 TIMx registers

### 8.4.1 CRC data register (CRC\_DR)

## 9. General IO (GPIO)

### 9.1 Introduction

Each general purpose IO port includes four 32-bit configuration registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, and GPIOx\_PUPDR), two 32-bit data registers (GPIOx\_IDR and GPIOx\_ODR), one 32-bit bit set/reset register (GPIOx\_BSRR), one 32-bit reset register (GPIOx\_BRR), one 32-bit lock register (GPIOx\_LCKR), and two 32-bit multiplex function select registers (GPIOx\_AFRH and GPIOx\_AFRL).

### 9.2 Main Features

- Up to 86 controlled IOs
- Output status: push-pull or open-drain + pull-up/pull-down
- Output from output data register (GPIOx\_ODR) or peripheral (multiplex function output) to pin
- Different speeds can be selected for each IO
- Input states: floating, pull-up/down, analog
- Input pins into data registers (GPIOx\_IDR) or peripherals (multiplexing function input)
- Set/reset register (GPIOx\_BSRR) with bitwise write privileges to GPIOx\_ODR
- Reset register (GPIOx\_BRR) with bitwise write privileges to GPIOx\_ODR
- Lock register (GPIOx\_LCKR) to freeze IO configuration
- Multiplexing function input/output select register (one IO can have up to 16 multiplexing functions)
- Fast flip, with as fast as two clock cycles per flip
- Pin multiplexing is very flexible, allowing IO pins to be used as GPIO or one of a variety of peripheral functions

### 9.3 Function description

Depending on the characteristics of each IO port listed in the datasheet, each port bit of a General Purpose IO (GPIO) port can be configured by software to multiple modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog function
- Open drain output with pull-up or pull-down function
- Push-pull output with pull-up or pull-down function
- Multiplexing function push-pull with pull-up or pull-down function
- Multiplexing function open drain with pull-up or pull-down function

Each IO port bit is freely programmable, but the IO port registers must be accessed by word, half-word, or byte. The GPIOx\_BSRR and GPIOx\_BRR registers allow independent access to reads/changes to any GPIO register. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The following diagram shows the basic structure of 5 V compatible and basic IO port bits. Table 9-1 shows possible port bit configuration schemes.

Figure 9-1 IO port basic structure

Table 9-1 Port bit configuration table

| MODE (i) [1: 0] | OTYPE | OSPEED (i) [1: 0] |   | PUPD (i) [1: 0] |   | IO configuration          |            |
|-----------------|-------|-------------------|---|-----------------|---|---------------------------|------------|
| 01              | 0     | SPEED [1: 0]      |   | 0               | 0 | GP output                 | PP         |

GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

### 9.3.1 General IO (GPIO)

During and immediately after the reset, the multiplexing function has not been activated, and most IO ports are configured in analog mode. After reset, the debug pin is in the multiplexing function pull-up/pull-down state and the BOOT0 pin is in the input mode pull-down state:

- PA15: JTDI in pull-up state
- PA14: JTCK/SWCLK in pull-down state
- PA13: JTMS/SWDAT in pull-up state

- PB4: NJTRST in pull-up state
- PB8: BOOT0 is in pull-down state

The input data register (GPIOx\_IDR) captures data from the IO pin every 1 AHB clock cycle.

All GPIO pins have internal weak pull-up and pull-down resistors that can be turned on/off based on the value in the GPIOx\_PUPDR register.

### 9.3.2 IO pin multiplexer and mapping

The IO pin is connected to the onboard peripheral/module via a multiplexer that allows the multiplexing function (AF) of only one peripheral to be connected to the IO pin at a time. This ensures that there are no collisions between peripherals sharing the same IO pin.

Each IO pin has a multiplexer with 16 multiplexing function inputs (AF0 to AF15) that can be configured through the GPIOx\_AFRL (for pins 0 to 7) and GPIOx\_AFRH (for pins 8 to 15) registers.

To configure IO to the desired functionality, follow these steps:

#### Debug assignment

After the system is reset, the debugging-related pins are multiplexed as AF for use by the system debugging interface.

#### GPIO

Configure the required IO as output or input in the GPIOx\_MODER register.

#### Peripheral multiplexing function

In the GPIOx\_AFRL or GPIOx\_AFRH register, the multiplexing function of IO is set

-Select output type, pull-up/pull-down, and output speed, respectively, via GPIOx\_OTYPER, GPIOx\_PUPDR, and GPIOx\_OSPEEDR registers

-Configure the required IO as multiplexing function in the GPIOx\_MODER register

#### Additional functions:

-For ADC, DAC, OPA and COMP, it is necessary to configure the corresponding IO into the analog mode through the register GPIOx\_MODER, and configure the corresponding functions in ADC, DAC, OPA and COMP; Special attention should be paid to the output of additional functions (such as DAC or OPA), the corresponding IO needs to be configured as analog mode first, and then the control registers of peripheral should be enabled.

-For additional functions TAMP\_RTC, WKUPx, PVD\_IN, OSC and OSC32, corresponding functions need to be configured in modules such as RTC, PWR and RCC, which take precedence over GPIO settings.

### 9.3.3 IO port control register

Each GPIO has four 32-bit control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR) and can be configured with up to 16 IOs. The GPIOx\_MODER register is used to select IO operating modes (input, output, multiplex, analog). GPIOx\_OTYPER is used to select the output type (push-pull or open drain). The GPIOx\_OSPEEDR register is used to set the IO speed. The GPIOx\_PUPDR register is used to select pull-up/pull-down.

### 9.3.4 IO port data register

Each GPIO has two 16-bit data registers: input and output data registers (GPIOx\_IDR and GPIOx\_ODR). GPIOx\_ODR stores the data to be output, it is read/write accessible. IO input data is stored in GPIOx\_IDR, which is a read-only register.

### 9.3.5 IO data bit operation

The Set Reset Register (GPIOx\_BSRR) is a 32-bit register that allows applications to set and reset individual data bits in the output data register (GPIOx\_ODR).

Each data bit in GPIOx\_ODR corresponds to two control bits in GPIOx\_BSRR: BS (i) and BR (i). When 1 is written, the BS (i) bit sets the corresponding ODR (i) bit. When 1 is written, the BR (i) bit clears the corresponding bit of ODR (i).

Writing any bit to 0 in GPIOx\_BSRR does not have any effect on the corresponding bit in GPIOx\_ODR. If both set and clear operations are attempted on a bit in GPIOx\_BSRR, the set operation takes precedence.

Using the GPIOx\_BSRR register to change the values of individual bits in GPIOx\_ODR is a “one-shot” effect that does not lock the GPIOx\_ODR bits. The GPIOx\_ODR bits can always be accessed directly. The GPIOx\_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx\_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

The reset register (GPIOx\_BRR) is a 32-bit register that allows an application to perform a reset operation on individual data bits in the output data register (GPIOx\_ODR). The reset register functions similarly to the set reset register, but can only reset one or more bits of the output data register.

### 9.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx\_LCKR register. The frozen registers include GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL, and GPIOx\_AFRH.

To perform a write operation to the GPIOx\_LCKR register, a specific write/read sequence must be used. After the software operates the LCKR [16] of this register with the correct locking sequence, the value of LCKR [15: 0] will be used to lock the configuration of IO (the value of LCKR [15: 0] must remain the same during the write sequence). After one or more ports are locked, they cannot be unlocked until a system reset occurs, or GPIO is reset. Each GPIOx\_LCKR bit freezes the corresponding bit in the control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH).

The lock sequence can only operate on the GPIOx\_LCKR register via word access.

Refer to the GPIOx\_LCKR register for specific operations.

### 9.3.7 IO multiplexing function input/output

There are two registers that can be used to select from the 16 multiplexing function inputs/outputs available for each IO.

Different multiplexed signals have different input/output directions, which are determined by their respective peripheral modules.

### 9.3.8 External interrupt line/wake-up line

All ports have external interrupt capability. To use an external interrupt line, the port must be configured in input mode, see the Interrupts and Events section.

### 9.3.9 Input configuration

When the IO port is configured as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- Each AHB clock sample pin level and is stored in the input data register
- Read the input data register to know the pin level

Figure 9-2 Input floating/pull-up/pull-down configuration

### 9.3.10 Output configuration

When an IO port is configured as an output:

- Output buffer enable
- Open-drain mode: '0' on the output register turns on N-MOS, while '1' on the output register puts the port in a high impedance state (PMOS is not conducting).
- Push-pull mode: '0' on the output register turns on N-MOS, while '1' on the output register turns on P-MOS.
- Schmitt Trigger Input Enable
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- Each AHB clock sample pin level and is stored in the input data register
- Read the input data register to know the pin level
- Read the output data register to know the value of the last GPIO write

Figure 9-3 Output configuration

### 9.3.11 Alternate function configuration

When an IO port is configured for multiplexing function:

- Output buffer enable
- The output data and output enable of the output buffer are driven by the peripheral module
- Schmidt Trigger Input Enable
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- Each AHB clock sample pin level and is stored in the input data register
- Read the output data register to know the value of the last GPIO write

Figure 9-4 Alternate function configuration

### 9.3.12 Analog configuration

When the IO port is configured in analog mode:

- The output buffer is not enabled;
- The Schmitt trigger input is not enabled, achieving zero power consumption on each analog IO pin. The output of the Schmitt trigger is forced to a constant value (0);
- Weak pull-up and pull-down resistors are disabled (software setting is required);
- Read access to the input data register gets the value "0".

Figure 9-5 High impedance-analog configuration

### 9.3.13 Use HSE or LSE oscillator pins as GPIO

When the HSE or LSE function is not enabled (the default after reset), the corresponding pin can be regarded as a normal GPIO.

When the HSE or LSE function is enabled (HSEON or LSEON is set in the RCC register), the functions of the relevant pins are controlled by the oscillator and are not affected by the settings of these GPIO registers.

When the crystal oscillator is configured in the user external clock mode, only OSC\_IN or OSC32\_IN is used to receive the external clock input, while the OSC\_OUT or OSC32\_OUT pin can still be used as the normal GPIO.

### 9.3.14 Use the GPIO pins in the RTC power domain

The PC13/PC14/PC15 GPIO function fails when the VDDD is powered down (when the device enters standby mode). If the RTC configuration does not override its GPIO settings, these pins are in an analog input/output state after standby wake-up.

### 9.3.15 Using PB8 as GPIO

PB8 can be used as a boot pin (BOOT0) or as a GPIO. Select based on the nSWBOOT0 bit in the user options byte:

- nSWBOOT0 = 1, BOOT0 pin in reset.
- nSWBOOT0 = 0, GPIO pin in reset.

Precautions:

PB8 is a GPIO pin regardless of nSWBOOT0 after reset.

### 9.3.16 Using PF5 as GPIO

PF5 can be used as a reset pin (NRST) or as a GPIO. According to the NRST\_MODE bit in the user options byte, it switches to the following mode:

- Reset input/output: NRST\_MODE = 2'b11(default) or NRST\_MODE = 2'b00

- Reset input only: NRST\_MODE =2'b01
- GPIO PF5 mode: NRST\_MODE =2'b10

## 9.4 TIMx registers

This section describes the register functionality of GPIO in detail

For a summary of register bits, register offset addresses, and reset values, see the GPIO register mapping table;

GPIO registers can be accessed by byte (8-bit), half-word (16-bit), or word (32-bit).

GPIOA base address: 0x4800\_0000

GPIOB base address: 0x4800\_0400

GPIOC base address: 0x4800\_0800

GIOD base address: 0x4800\_0C00

GPIOE base address: 0x4800\_1000

GPIOF base address: 0x4800\_1400

### 9.4.1 GPIO Port Mode Register (GPIOx\_MODER) (x = A.. F)

Address offset: 0x00

Reset value: 0xABFF\_FFFF (port A)

Reset value: 0xFFFF\_FEBF (port B)

Reset Value: 0xFFFF FFF (Other C.. F)

#### 9.4.8 GPIO Port Configuration Lock Register (GPIOx\_LCKR) (x = A.. F)

This register is used to lock the configuration of the port bits when the correct write sequence set LCKK is performed. LCKR [15: 0] is used to lock the configuration of GPIO ports. The LCKR [15: 0] cannot be changed during a specified write operation. After performing the locking sequence on the corresponding port, the configuration of the port bits can no longer be changed until the next system reset. Note: A specific write sequence is used to write to the GPIOx\_LCKR register. Only word access is allowed in lock timing.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

## 10. System configuration controller (SYSCFG)

### 10.1 Main features

The SYSCFG module provides the following functions:

- I2C IO Noise Filter Control
- I2C Fm + Mode control
- All IO Noise Filter Control
- EXTI IO Selection
- Analog Channel 2 Control
- Mapping the initial program area according to different boot modes
- DMA Peripheral Channel Selection
- Timer brake input and external trigger control
- CCM erase control, CCM busy status flag
- Parity control of SRAM1 and CCM
- CCM page write protection

### 10.2 TIMx registers

#### 10.2.1 SYSCFG configuration register 1 (SYSCFG\_CFGR1)

Address offset: 0x00

Reset value: 0x0000 000x (x depends on the boot mode configuration in the BOOT0 pin and options byte)

# 11. Peripheral interconnection matrix

## 11.1 Introduction

Some peripherals have connectivity relationships with each other.

This allows autonomous communication between peripherals, thereby saving CPU resources while also saving power consumption. In addition, these hardware connections eliminate software latency.

Depending on the peripheral, these interconnections can operate in run, sleep, and stop modes.

### 11.2.7 TI4

Table 11-7 Interconnect 7

| Timer TI4 Input signal | Timer TI4 Signal allocation |           |      |           |      |      |       |
|------------------------|-----------------------------|-----------|------|-----------|------|------|-------|
|                        | TIM1                        | TIM2      | TIM3 | TIM4      | TIM5 | TIM8 | TIM18 |
| timx_ti4_in0           | TI4                         |           | TI4  | TI4       | TI4  | TI4  | TI4   |
| timx_ti4_in1           |                             | Comp1_out |      | Comp3_out |      |      |       |
| timx_ti4_in1           |                             | Comp2_out |      |           |      |      |       |

### 11.2.8 break1

Table 11-8 Interconnect 8

|                      | Timer Brake 1 Signal Distribution |              |               |               |               |
|----------------------|-----------------------------------|--------------|---------------|---------------|---------------|
|                      | TIM1_break                        | TIM8_break   | TIM15_break   | TIM16_break   | TIM17_break   |
|                      | TIM1_BKINpin                      | TIM8_BKINpin | TIM15_BKINpin | TIM16_BKINpin | TIM17_BKINpin |
| Timer Brake 1 Source | Comp1_out                         | Comp1_out    | Comp1_out     | Comp1_out     | Comp1_out     |

|  |           |           |           |           |           |
|--|-----------|-----------|-----------|-----------|-----------|
|  | Comp2_out | Comp2_out | Comp2_out | Comp2_out | Comp2_out |
|  | Comp3_out | Comp3_out | Comp3_out | Comp3_out | Comp3_out |
|  | Comp4_out | Comp4_out | Comp4_out | Comp4_out | Comp4_out |

The timer's brake input has two channels:

1. break1 channel, which includes application failures and system failures.
2. The break2 channel only includes application failures.

### 11.2.9 break2

Table 11-9 Interconnect 9

|                      | Timer Brake 2 Signal Distribution |               |
|----------------------|-----------------------------------|---------------|
|                      | TIM1_break2                       | TIM8_break2   |
| Timer Brake 2 Source | TIM1_BKIN2pin                     | TIM8_BKIN2pin |
|                      | Comp1_out                         | Comp1_out     |
|                      | Comp2_out                         | Comp2_out     |
|                      | Comp3_out                         | Comp3_out     |
|                      | Comp4_out                         | Comp4_out     |
|                      | Comp4_out                         | Comp4_out     |

### 11.2.10 Comparator blanking source

Table 11-10 Interconnect 10

|                            | Comparator blanking source allocation |           |           |           |
|----------------------------|---------------------------------------|-----------|-----------|-----------|
|                            | COMP1                                 | COMP2     | COMP3     | COMP4     |
| Comparator blanking source | tim1_oc5                              | tim1_oc5  | tim1_oc5  | tim3_oc4  |
|                            | tim2_oc3                              | tim2_oc3  | tim3_oc3  | tim8_oc5  |
|                            | tim3_oc3                              | tim3_oc3  | tim2_oc4  | tim15_oc2 |
|                            | tim8_oc5                              | tim8_oc5  | tim8_oc5  | tim1_oc5  |
|                            | tim18_oc3                             | tim18_oc3 | tim18_oc4 | tim18_oc4 |
|                            | tim15_oc1                             | tim15_oc1 | tim15_oc1 | tim15_oc1 |
|                            | tim4_oc3                              | tim4_oc3  | tim4_oc3  | tim4_oc3  |

TIMx can be used as a blanking window for COMPx.

The output signal TIMx\_OCx of the timer is the blanking source input of COMPx.

### 11.2.11 IRTIM control signal

Table 11-11 Interconnect 11

|                           |                                 |
|---------------------------|---------------------------------|
| IRTIM control signal      | IRTIM Control Signal Allocation |
| Modulated envelope signal | Tim16_oc1                       |
| Carrier signal            | Tim17_oc1                       |

The general purpose timer (TIM16/TIM17) output channel TIMx\_OC1 is used to generate the waveform output of the infrared signal.

### 11.2.12 System error

Table 11-12 Interconnect 12

| System Error Source | System error signal is assigned to Timer signal |         |          |          |          |

|                     | TIM1                                            | TIM8    | TIM15    | TIM16    | TIM17    |
| Flash ECC error     | TIM1_BK                                         | TIM8_BK | TIM15_BK | TIM16_BK | TIM17_BK |
| PVD output          |                                                 |         |          |          |          |
| SRAM1/CCM parity    |                                                 |         |          |          |          |
| Cortex-M4F Lockup   |                                                 |         |          |          |          |
| CSS                 |                                                 |         |          |          |          |

## 12. DMA Controller (DMA)

### 12.1 Overview

Direct memory access (DMA) is used to provide high-speed data transfer between peripherals and memory, between memory and memory, or between peripherals and peripherals. Data can be quickly moved by DMA without any CPU actions. This keeps the CPU resources free for other operations. The two DMA controllers have a total of 12 channels (6 channels for DMA1 and 6 channels for DMA2), and each channel is dedicated to managing access requests from one or more peripheral devices. The DMA also has an arbiter to coordinate the priorities of individual DMA requests.

#### 12.1.1 Main features

The DMA supports:

- Single AHB Master
- There is programmable channel priority
- Supports peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Supports on-chip memory devices (such as Flash, SRAM, AHB, and APB peripherals) as source and destination
- Supports programmable source and destination addresses, the addresses can be optionally incremented, decremented or unchanged
- The multi-block transfer function can be realized by automatic reloading of channel registers and consecutive addresses between blocks
- Supports programmable burst transaction sizes
- Each channel generates an interrupt request. Each interrupt request is caused by any of six DMA events: Transfer Complete, Block Transfer Complete, Source Transaction Complete, Destination Transaction Complete, Transfer Error, or Half Block Transfer Complete
- The FIFO depth of channels 0 to 4 is 8 bytes, and the FIFO depth of channel 5 is 32 bytes

#### 12.1.2 Basic definition

- Source Peripheral-A device located on the AHB layer from which the DMA can read data, which then stores in the channel FIFO. The source peripheral forms a channel together with the target peripheral. The source peripheral is an AHB or APB slave. If the source is an APB slave, it is accessed through the AHB-APB bridge.
- Destination peripheral-The device to which the DMA writes data stored in the FIFO (previously read from the source peripheral). The target peripheral is an AHB or APB slave. If the target is an APB slave, it is accessed through the AHB-APB bridge.
- Memory-The source or destination is always ready for a DMA transfer and does not need to have a handshake interface with the DMA.
- Channel-The path through which read/write data occurs via FIFO between a source peripheral on a configured AHB layer and a target peripheral on the same or different AHB layer. If the source peripheral is not memory, the source handshake interface is assigned to the channel. If the target peripheral is not memory, the target handshake interface is assigned to the channel. Source and

destination handshake interfaces can be dynamically allocated by programming channel registers.

- **Flow Controller**-The device (DMA source or destination peripheral) that determines the DMA block transmission length and terminates it.
- **Transport Hierarchy** Figure 12-1 shows the hierarchy between DMA transmissions, block transmissions, transactions (single or burst), and AHB transmissions (single or burst) for non-memory peripherals

Figure 12-1 DMA transfer hierarchy for non-memory peripherals

Figure 12-2 DMA Transfer Hierarchy of Graph Memory

- **Block**-A block of DMA data, the number of which is the block length, determined by the flow controller. For transfers between DMA and memory, a block is directly decomposed into a series of bursts and individual transfers. For transfers between DMA and non-memory peripherals, a block is broken down into sequences of DMA transactions (single and burst).
- **Transaction**-The basic unit of DMA transmission, determined by a hardware or software handshake interface. If the peripheral is a non-memory device, then the transaction is only related to the transfer between the source or destination peripheral of the DMA.
- There are two kinds of transactions:
  - **Single Transaction**-The length of a single transaction is always 1 and converted to a single AHB transfer.
  - **Burst Transaction**-The length of a burst transaction can be configured. A burst transaction is

converted into a series of bursts and an AHB single transmission. The burst transaction length is controlled by the program, and usually has a certain relationship with the FIFO size of DMA, source peripheral and target peripheral.

- **DMA Transfer**-The software controls the number of blocks for DMA transmission. After the DMA transfer is complete, the hardware in the DMA disables the channel and generates an interrupt to indicate that the DMA transfer is complete. The channel can then be reprogrammed for the new DMA transmission.
  - **Monoblock DMA transmission**-consists of a single block.
  - **Multi-block DMA transmission**-A DMA transmission may consist of multiple DMA blocks. Multi-block DMA transfers are supported by automatic reloading of channel registers and contiguous blocks.
    - ◆ **Automatic Reload**-DMA automatically reloads the value when the channel was first enabled into the channel register at the end of each block.
    - ◆ **Contiguous Blocks**-The address between contiguous blocks is selected as a continuation of the end of the previous block.

### 12.1.3 Top-level structure diagram

The DMA and CPU share the system bus. If the DMA and CPU access the same destination (memory or peripheral), the DMA request will stop the CPU from accessing the system bus for some clock cycles. Bus matrix arbitration uses the round-robin method to ensure that the CPU occupies at least half of the system bus bandwidth.

## 12.2 Functional description

### 12.2.1 Interface definition

Source single transaction size in bytes:  $\text{src\_single\_size\_bytes} =$

$\text{DMA\_CH\_CTRLLx.SRC\_TR\_WIDTH}/8$

Source burst transaction size in bytes ):  $\text{src\_burst\_size\_bytes} = \text{DMA\_CH\_CTRLLx.SRC\_MSIZE} * \text{src\_single\_size\_bytes}$

Target single transaction size in bytes:  $\text{dst\_single\_size\_bytes} =$

$\text{DMA\_CH\_CTRLLx.DST\_TR\_WIDTH}/8$

Target burst transaction size in bytes ):  $\text{dst\_burst\_size\_bytes} = \text{DMA\_CH\_CTRLLx.DST\_MSIZE} * \text{dst\_single\_size\_bytes}$

Block size in bytes ):  $\text{blk\_size\_bytes\_dma} = \text{DMA\_CH\_CTRLHx.BLOCK\_TS} * \text{src\_single\_size\_bytes}$

### 12.2.2 Memory peripheral

$\text{DMA\_CH\_CTRLLx.SRC\_MSIZE}$  and  $\text{DMA\_CH\_CTRLLx.DST\_MSIZE}$  are only valid for peripherals with handshake interfaces, and they cannot be used to define burst lengths of memory peripherals.

Consequently:

- The length of the burst transfer to the memory is always equal to the number of data items available in the channel FIFO or the number of data items required to complete the block transfer, whichever is smaller.
- The length of a burst transfer from the memory is always equal to the space available in the channel FIFO or the number of data items required to complete the block transfer, whichever is smaller.

### 12.2.3 DMA transmission

DMA block transfers may be requested from peripherals or triggered by software in the case of memory-to-memory transfers.

After the event, a single DMA transfer step:

- The peripheral sends a DMA request signal to the DMA controller.
- The DMA controller responds to the request according to the priority of the channel associated with this peripheral request.
- Once the DMA controller grants the peripheral, the transmission is initiated, and when the transmission is complete, the DMA controller sends a reply to the peripheral.
- When the peripheral receives an answer from the DMA controller, it releases its request.
- Once the peripheral cancels the request assertion, the DMA controller releases the channel currently occupied by the peripheral.

The request/acknowledgement protocol is used when the peripheral is the source or destination of the transmission. For example, in a memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the DMA controller. The DMA controller then writes the data from the FIFO to the peripheral.

For a given channel x, a DMA block transmission consists of the following repetitive sequence:

- Data read from a peripheral data register or a location in memory, the data bit width is configured in the DMA\_CH\_CTRLx.SRC\_TR\_WIDTH register, the data length is configured in the DMA\_CH\_CTRLx.SRC\_MSIZ register, addressed through the internal current source address register, and the start address for the first transfer is configured in the DMA\_SARx register.
- Data is written to a peripheral data register or a location in memory, the data bit width is configured in the DMA\_CH\_CTRLx.DST\_TR\_WIDTH register, the data length is configured in the DMA\_CH\_CTRLx.DST\_MSIZ register, addressed through the internal current destination address register, and the start address for the first transfer is configured in the DMA\_DARx register.
- The DMA\_CTLx.BLOCK\_TS register contains the number of data items remaining to be transferred, which indicates the total number of data items that have been read from the source after DMA initiates the transfer.

The above sequence is repeated until the set value of the DMA\_CTLx.BLOCK\_TS register is reached.

#### 12.2.4 Arbiter

The arbiter initiates access to the peripheral/memory according to the priority of the channel request.

When a request channel x is granted (hardware-requested or software-triggered) access by the arbiter, a single or burst DMA transmission is made. The arbiter then again arbitrates all requested channels and selects the channel with the highest priority.

The priority of each channel can be set in the DMA\_CH\_CFGx register, and there are 6 levels:

- ✓ 0
- ✓ 1
- ✓ 2
- ✓ 3
- ✓ 4
- ✓ 5

Priority  $5 > 4 > 3 > 2 > 1 > 0$ .

A channel with a lower channel number at the same priority has a higher priority.

#### 12.2.5 DMA channel

##### 12.2.5.1 Programmable data sizes

Each channel can be DMA transferred between peripheral registers with fixed addresses and memory addresses. The amount of data transferred by DMA is programmable, up to 4095.

##### 12.2.5.2 Pointer incrementation

By setting the SINC and DINC flag bits in the DMA\_CH\_CTRLx register, pointers to peripherals and memory can be selectively autoincremented after each transfer.

When set to incremental mode, the next address to be transferred will be the previous address plus an incremental value, which depends on the selected data width of 8/16/32 bits. The first address transferred is the address stored in the DMA\_SAx/DMA\_DAx register. During transfer, these registers maintain their initial values, and the software cannot change and read out the address currently being transferred (in the internal current peripheral/memory address register).

When the channel is configured to transmit in a single block, DMA operations will no longer occur after the transmission ends (i.e. the transmission count becomes 0). To start a new DMA transfer, the number of transfers needs to be re-written in the DMA\_CH\_CTRLHx.BLOCK\_TS register with the DMA channel closed.

### 12.2.5.3 Memory-to-memory mode

The operation of the DMA channel can be performed without peripheral requests. This operation is memory-to-memory mode. When the DMA\_CH\_CTRLx.TT register is set, the DMA transfer will begin as soon as the software sets the CH\_EN bit in the DMA\_CH\_ENx register to start the DMA channel. When the number of transferred data reaches the set value of the DMA\_CH\_CTRLx.BLOCK\_TS register, the DMA transfer ends.

### 12.2.6 Error handling

When an error occurs in an AHB transfer, the following happens:

1. Ongoing DMA transmission stops immediately
2. Related channel is disabled
3. Issue interrupt (if not masked)

If multiple channels are open, only the channels where AHB errors are detected are closed.

The contents of the FIFO are not cleared and become inaccessible and overwritten once the channel is re-enabled to initiate a new transfer.

Automatic resumption of transmission from the point where the error occurred is not supported, and the entire block transmission must be restarted to retransmit.

### 12.2.7 Interrupts and events

For each channel, there are six types of interrupt sources:

- Block Transfer Completion Interrupt

This interrupt is generated when the DMA block transmission is complete.

- Destination transaction completion interrupt

This interrupt is generated after the last AHB transmission of the requested single/burst transaction is completed from the handshake interface (hardware or software) of the target.

If the target of a channel is memory, then the channel will never generate a target transaction completion interrupt. Therefore, the corresponding enable of this interrupt does not work.

- Error interrupt

This interrupt occurs when an error response is received from an AHB slave on the bus during a DMA transmission. In addition, generating an error interrupt cancels the DMA transmission and disables the channel.

- Source transaction completion interrupt

This interrupt is generated after the last AHB transfer of the requested single/burst transaction is completed from the source's handshake interface (hardware or software).

If the source is memory, then the source transaction completion interrupt should be ignored because memory does not have the concept of "DMA Transaction Level".

- DMA transmission completely interrupted

This interrupt is generated when a DMA transfer to the target peripheral is completed.

- Half-block transmission completion interrupt

This interrupt is generated when half of the transmission of the DMA block is complete to the target peripheral.

### 12.2.8 DMAMUX mapping

DMA peripheral requests are mapped to each channel of DMA1 (6 channels) or DMA2 (6 channels), which is controlled by the DMAx\_MAP register of SYSCFG. Each peripheral request can be mapped to any of the 12 channels through configuration.

The relationship between sequence number and peripheral request is shown in the following table:

| DMA request MUX input | Source     | DMA request MUX input | Source    | DMA request MUX input | Source       |
|-----------------------|------------|-----------------------|-----------|-----------------------|--------------|
| 0                     | ADC1       | 32                    | TIM1_TRIG | 64                    | TIM5_CH4     |
| 1                     | ADC2       | 33                    | TIM1_COM  | 65                    | TIM5_UP      |
| 2                     | ADC3       | 34                    | TIM8_CH1  | 66                    | TIM5_TRIG    |
| 3                     | DAC1       | 35                    | TIM8_CH2  | 67                    | TIM18_CH1    |
| 4                     | DAC2       | 36                    | TIM8_CH3  | 68                    | TIM18_CH2    |
| 5                     | SPI1_RX    | 37                    | TIM8_CH4  | 69                    | TIM18_CH3    |
| 6                     | SPI1_TX    | 38                    | TIM8_UP   | 70                    | TIM18_CH4    |
| 7                     | SPI2_RX    | 39                    | TIM8_TRIG | 71                    | TIM18_UP     |
| 8                     | SPI2_TX    | 40                    | TIM8_COM  | 72                    | TIM18_TRIG   |
| 9                     | SPI3_RX    | 41                    | TIM6_UP   | 73                    | TIM15_CH1    |
| 10                    | SPI3_TX    | 42                    | TIM7_UP   | 74                    | TIM15_CH2    |
| 11                    | USART1_RX  | 43                    | TIM2_CH1  | 75                    | TIM15_UP     |
| 12                    | USART1_TX  | 44                    | TIM2_CH2  | 76                    | TIM15_TRIG   |
| 13                    | USART2_RX  | 45                    | TIM2_CH3  | 77                    | TIM15_COM    |
| 14                    | USART2_TX  | 46                    | TIM2_CH4  | 78                    | TIM16_CH1    |
| 15                    | USART3_RX  | 47                    | TIM2_UP   | 79                    | TIM16_UP     |
| 16                    | USART3_TX  | 48                    | TIM2_TRIG | 80                    | TIM17_CH1    |
| 17                    | LPUART1_RX | 49                    | TIM3_CH1  | 81                    | TIM17_UP     |
| 18                    | LPUART1_TX | 50                    | TIM3_CH2  | 82                    | AES_in       |
| 19                    | I2C1_RX    | 51                    | TIM3_CH3  | 83                    | AES_OUT      |
| 20                    | I2C1_TX    | 52                    | TIM3_CH4  | 84                    | Cordic_Read  |
| 21                    | I2C2_RX    | 53                    | TIM3_UP   | 85                    | Cordic_Write |
| 22                    | I2C2_TX    | 54                    | TIM3_TRIG | 86                    | ESMC_RX      |
| 23                    | I2C3_RX    | 55                    | TIM4_CH1  | 87                    | ESMC_TX      |
| 24                    | I2C3_TX    | 56                    | TIM4_CH2  | 88                    | SDIO         |
| 25                    | I2C4_RX    | 57                    | TIM4_CH3  | 89                    | UART1_RX     |
| 26                    | I2C4_TX    | 58                    | TIM4_CH4  | 90                    | UART1_TX     |
| 27                    | TIM1_CH1   | 59                    | TIM4_UP   | 91                    | UART2_RX     |
| 28                    | TIM1_CH2   | 60                    | TIM4_TRIG | 92                    | UART2_TX     |
| 29                    | TIM1_CH3   | 61                    | TIM5_CH1  | 93                    | UART3_RX     |
| 30                    | TIM1_CH4   | 62                    | TIM5_CH2  | 94                    | UART3_TX     |
| 31                    | TIM1_UP    | 63                    | TIM5_CH3  | 95                    | LCDC_TX      |

## 12.2.9 Software Application Description

### 12.2.9.1 DMA Transmission Type

The DMA transmission may consist of a single or multiple block transmissions. On contiguous blocks of multi-block transfer, the S<sub>A</sub>x/D<sub>A</sub>x registers in the DMA are reprogrammed using one of the following methods:

- Automatic reload
- Continuous addresses between blocks

On contiguous blocks of multi-block transfers, the CH\_CTRL<sub>x</sub> register in the DMA is reprogrammed using the following method:

- Automatic reload

### 12.2.9.2 Multi-block transmission

Multiblock transmission does not support exchanging source and destination during transmission.

Table 12-1 Programming of transfer types and channel register update methods

| Transmission Type                                                         | RELOAD_SRC (CH_CFGL <sub>x</sub> ) | RELOAD_DST (CH_CFGL <sub>x</sub> ) | CH_CTRL <sub>x</sub> Update Method | S <sub>A</sub> x Update Method | D <sub>A</sub> x update method |
|---------------------------------------------------------------------------|------------------------------------|------------------------------------|------------------------------------|--------------------------------|--------------------------------|
| 1. Last transmission of a single or multiple blocks                       | 0                                  | 0                                  | None, reprogrammed                 | None                           | None                           |
| 2. Automatic reload multi-block transmission, S <sub>A</sub> continuous   | 0                                  | 1                                  | Load initial values                | Continuous                     | Automatic reload               |
| 3. Automatic overload multi-block transmission, D <sub>A</sub> continuous | 1                                  | 0                                  | Load the initial value.            | Automatic reload               | Continuous                     |
| 4. Automatic reload multi-block transmission                              | 1                                  | 1                                  | Load the initial value.            | Automatic reload               | Automatic reload               |

#### Automatic reload channel register

During automatic reloading, the channel registers are reloaded at each block completion with their initial values and a new value for the new block. Depending on the number of rows in Table 12-1, some or all of the S<sub>A</sub>x, D<sub>A</sub>x, and CH\_CTRL<sub>x</sub> channel registers are reloaded from their initial values at the beginning of the block transfer.

#### Continuous addresses between blocks

In this case, the address between consecutive blocks is selected as a continuation of the end of the previous block.

Continuing the source or destination address between blocks is a function of the CH\_CFGL<sub>x</sub>.RELOAD\_SRC and CH\_CFGL<sub>x</sub>.RELOAD\_DST registers (see Table12-1).

You cannot select both S<sub>A</sub>x and D<sub>A</sub>x updates as consecutive updates. If you want to use this function, you should increase the size of the block transfer (CH\_CTRL<sub>Hx</sub>.BLOCK\_TS).

### Suspend transmission between blocks

At the end of each block transmission, a block end interrupt is asserted in the following cases:

1. Interrupt enable, CH\_CTRLx.INT\_EN = 1
2. The channel block interrupt is unmasked, MASKBLOCK [n] = 1, where n is the channel number

For rows 2, 3, and 4 in Table 12-1 (SAX and/or DAX are automatically reloaded between block transmissions), if the block end interrupt is enabled and unmasked, the DMA transmission automatically stops after the block end interrupt.

The DMA does not proceed to the next block transfer until the hardware detects a write to the CLEARBLOCK [n] block interrupt clearing register (done by software to clear the channel block complete interrupt).

For rows 2, 3, and 4 in Table 12-1 (SAX and/or DAX are automatically reloaded between block transmissions), DMA transmissions do not stop if:

- Interrupt not enabled, CH\_CTRLx.INT\_EN = 0
- Channel block interrupts are masked, MASKBLOCK [n] = 0, where n is the channel number
- Suspend in block transfer completion interrupt not enabled, CH\_CFGLx.INT\_SUP = 0

The channel pause between blocks is used to ensure that the end-of-block ISR (interrupt service routine) of the penultimate block is served before the last block starts. This ensures that the ISR has cleared the CH\_CFGLx.RELOAD\_SRC and/or CH\_CFGLx.RELOAD\_DST bits before completing the final block. For the second-to-last block transmission, the overload bits CH\_CFGLx.RELOAD\_SRC and/or CH\_CFGLx.RELOAD\_DST should be cleared in the block end ISR of the second-to-last block.

### End Multiblock Transmission

All multi-block transmissions must end in line 1 of Table 12-1. At the end of each block transmission, the DMA will sample the row number. If the DMA is in the row 1 state, the previous block transmitted is the last block and the DMA transmission terminates.

For rows 2, 3, and 4 of Table 12-1 (CH\_CFGLx.RELOAD\_SRC and/or CH\_CFGLx.RELOAD\_DST settings), the multi-block DMA transfer continues until the CH\_CFGLx.RELOAD\_SRC and CH\_CFGLx.RELOAD\_DST registers are cleared by the software. They should be programmed to 0 in the end of block interrupt service routine that serves the penultimate block transfer, which will put the DMA into the state of the first line.

#### 12.2.9.3 Programming channel

Two registers, CH\_CTRLx and CH\_CFGx, need to be programmed to determine whether a single block transfer or a multi-block transfer occurs, and which type of multi-block transfer is used. Transmission types are shown in Table 12-1.

#### Monoblock Transfer (Line 1)

1. Read the channel enable register to select a free channel, refer to the CH\_EN register.
2. Clear any pending interrupts on channels in previous DMA transmissions by writing interrupt clearing registers: CLEARTRF, CLEARBLOCK, CLEARSRCTRAN, CLEARDSTTRAN,

CLEARERR, and CLEARHALFBLOCK. Reading the interrupt raw status and interrupt status registers confirms that all interrupts have been cleared.

3. Program the following channel registers:
  - a) Write the starting source address of channel x in the Sx register.
  - b) Write the start destination address of channel x in the Dx register.
  - c) Program CH\_CTRLx and CH\_CFGx as per row1 of Table12-1.
  - d) The control information of the DMA transfer is written in the CH\_CTRLx register of channel x. For example, the following can be programmed in the register:
    - i. The transfer type (memory or non-memory peripheral of source and destination) is set by programming the TT of the CH\_CTRLx register.
    - ii. Set transfer properties, such as:
      - ✧ Transmission width of source in SRC\_TR\_WIDTH field
      - ✧ Transmission width of the target in the DST\_TR\_WIDTH field
      - ✧ Incremental/decremental or fixed address of source in SINC field
      - ✧ Increment/decrement or fixed address of the target in the DINC field
  - e) Write channel configuration information to the CH\_CFGx register of channel x
    - i. Specify the handshake interface type (hardware or software) of the source peripheral and the target peripheral, which is not required for the memory. This step requires programming the HS\_SEL\_SRC/HS\_SEL\_DST bits separately. Write 0 activates the hardware handshake interface to handle source/destination requests. Write 1 activates the software handshake interface to handle source and destination requests.
    - ii. If the hardware handshake interface is activated for the source or destination peripheral, the handshake interface is assigned to the source and destination peripherals, which requires programming of the SRC\_PER and DST\_PER bits, respectively.
4. Before writing to CH\_EN, make sure the DMA\_EN register is enabled.
5. To transmit a data block (assuming a non-memory peripheral), the source and target request a single and burst DMA transaction. The DMA acknowledges and performs block transmission upon completion of each transaction (burst and single) in the block.
6. Once the transfer is complete, the hardware sets the interrupt and disables the channel. At this point, you can respond to block transfer completion or transfer completion interrupt, or poll the transfer completion raw interrupt status register (RAWTFR [n], n = channel number) until it is set by hardware in order to detect when the transfer is complete. Note that if this kind of polling is used, the software must ensure that the transfer completion interrupt is cleared by writing the interrupt clearance register CLEARTFR [n] before the channel is enabled.

#### **Multi-block transmission with source address auto-reloading and destination address auto-reloading (line 4)**

1. Read the channel enable register to select a free channel, refer to the CH\_EN register.

2. Clear any pending interrupts on channels in previous DMA transmissions by writing interrupt clearing registers: `CLEARTRF`, `CLEARBLOCK`, `CLEARSRCTRAN`, `CLEARSTTRAN`, `CLEARERR`, and `CLEARHALFBLOCK`. Reading the interrupt raw status and interrupt status registers confirms that all interrupts have been cleared.
3. Program the following channel registers:
  - a) Write the starting source address of channel x in the `SAX` register.
  - b) Write the start destination address of channel x in the `DAX` register.
  - c) Program `CH_CTRLx` and `CH_CFGx` as per line 4 of Table 12-1.
  - d) The control information of the DMA transfer is written in the `CH_CTRLx` register of channel x. For example, the following can be programmed in the register:
    - i. By programming the `TT` of the `CH_CTRLx` register, the transfer type (memory or non-memory peripherals of the source and destination) and the flow control device are set.
    - ii. Set transfer properties, such as:
      - ✧ Transmission width of source in `SRC_TR_WIDTH` field
      - ✧ Transmission width of the target in the `DST_TR_WIDTH` field
      - ✧ Incremental/decremental or fixed address of source in `SINC` field
      - ✧ Increment/decrement or fixed address of the target in the `DINC` field
  - e) Write channel configuration information into the `CH_CFGx` register of channel x. Ensure that `CH_CFGx.RELOAD_SRC` and `CH_CFGx.RELOAD_DST` are enabled.
    - i. Specifies the handshake interface type (hardware or software) of the source and destination peripherals, which is not required for the memory. This step requires programming the `HS_SEL_SRC/HS_SEL_DST` bits separately. Write 0 activates the hardware handshake interface to handle source/destination requests. Write 1 activates the software handshake interface to handle source and destination requests.
    - ii. If the hardware handshake interface is activated for the source or destination peripheral, the handshake interface is assigned to the source and destination peripherals, which requires programming of the `SRC_PER` and `DST_PER` bits, respectively.
4. Before writing to `CH_EN`, make sure the `DMA_EN` register is enabled.
5. To transmit a data block (assuming a non-memory peripheral), the source and target request a single and burst DMA transaction. The DMA acknowledges and performs block transmission upon completion of each transaction (burst and single) in the block.
6. When block transfer is complete, the DMA reloads the `SAX`, `DAX`, and `CH_CTRLx` registers. The hardware setup block completes the interrupt. The DMA then samples the row numbers as shown in Table 12-1. If the DMA is in line 1, then the DMA transfer has completed. The hardware sets the transfer completion interrupt and disables the channel. You can respond to a block transfer completion or a transfer completion interrupt, or poll the transfer completion raw interrupt status register (`RAWTRF[n]`, where n is the channel number) until it is set by hardware.

in order to detect when the transfer is complete. Note that if this kind of polling is used, the software must ensure that the transfer completion interrupt is cleared by writing the interrupt clearance register `CLEAR_TFR[n]` before the channel is enabled. If the DMA is not in line 1, the next step is performed.

7. The DMA transfer process is as follows:

- a) If the interrupt is enabled (`CH_CTRLx.INT_EN = 1`), and the block completion interrupt is unmasked (`MASK_BLOCK[x] = 1'b1`, where `x` is the channel number), the hardware sets the block completion interrupt when the block transfer is complete. It then stops running until the block transfer completion interrupt is cleared by the software. If the next block is the last block in the DMA transfer, the block completion ISR (interrupt service routine) should clear the reload registers `CH_CFGx.RELOAD_SRC` and `CH_CFGx.RELOAD_DST` in `CH_CFGx`. This puts the DMA on row 1, as shown in Table 12-1. If the next block is not the last block in the DMA transfer, then the reload register should remain enabled to keep DMA on line 4.
- b) If the interrupt is disabled (`CH_CTRLx.INT_EN = 0`) or the block completion interrupt is masked (`MASK_BLOCK[x] = 1'b0`, where `x` is the channel number), then the hardware does not stop until the write block transfer completion interrupt clear register is detected; Instead, it starts the next block transfer immediately. In this case, the software must clear the reload registers `CH_CFGx.RELOAD_SRC` and `CH_CFGx.RELOAD_DST` in `CH_CFGx` before the last block of the DMA transfer is complete, thereby putting the DMA in line 1 of Table 12-1.

**Multiblock transmission with source address automatic reload and destination address contiguity (line 3)**

1. Read the channel enable register to select a free channel, refer to the `CH_EN` register.
2. Clear any pending interrupts on channels in previous DMA transmissions by writing interrupt clearing registers: `CLEAR_TFR`, `CLEAR_BLOCK`, `CLEAR_SRCTAN`, `CLEAR_DSTTRAN`, `CLEAR_ERR`, and `CLEAR_HALF_BLOCK`. Reading the interrupt raw status and interrupt status registers confirms that all interrupts have been cleared.
3. Program the following channel registers:
  - a) Write the starting source address of channel `x` in the `SAX` register.
  - b) Write the start destination address of channel `x` in the `DAX` register.
  - c) Program `CH_CTRLx` and `CH_CFGx` as per row 3 of Table 12-1.
  - d) The control information of the DMA transfer is written in the `CH_CTRLx` register of channel `x`. For example, the following can be programmed in the register:
    - i. The transfer type (memory or non-memory peripheral of source and destination) is set by programming the `TT` of the `CH_CTRLx` register.
    - ii. Set transfer properties, such as:
      - ✧ Transmission width of source in `SRC_TR_WIDTH` field

- ✧ Transmission width of the target in the `DST_TR_WIDTH` field
  - ✧ Incremental/decremental or fixed address of source in `SINC` field
  - ✧ Increment/decrement or fixed address of the target in the `DINC` field
- e) Write channel configuration information into the `CH_CFGx` register of channel x. Ensure that `CH_CFGLx.RELOAD_SRC` is enabled and `CH_CFGLx.RELOAD_DST` is disabled.
    - i. Specify the handshake interface type (hardware or software) of the source peripheral and the target peripheral, which is not required for the memory.  
 This step requires programming the `HS_SEL_SRC/HS_SEL_DST` bits separately. Write 0 activates the hardware handshake interface to handle source/destination requests. Write 1 activates the software handshake interface to handle source and destination requests.
    - ii. If the hardware handshake interface is activated for the source or destination peripheral, the handshake interface is assigned to the source and destination peripherals, which requires programming of the `SRC_PER` and `DST_PER` bits, respectively.
  4. Before writing to `CH_EN`, make sure the `DMA_EN` register is enabled.
  5. To transmit a data block (assuming a non-memory peripheral), the source and target request a single and burst DMA transaction. The DMA acknowledges and performs block transmission upon completion of each transaction (burst and single) in the block.
  6. When the block transfer is complete, the DMA reloads the `Sx` register and the `Dx` register remains unchanged. The hardware setup block completes the interrupt. The DMA then samples the row numbers as shown in Table 12-1. If the DMA is in line 1, then the DMA transfer has completed. The hardware sets the transfer completion interrupt and disables the channel. You can respond to a block transfer completion or a transfer completion interrupt, or poll the transfer completion raw interrupt status register (`RAWTFR [n]`,  $n = \text{channel number}$ ) until it is set by hardware in order to detect when the transfer is complete. Note that if this kind of polling is used, the software must ensure that the transfer completion interrupt is cleared by writing the interrupt clearance register `CLEAR_TFR [n]` before the channel is enabled. If the DMA is not in line 1, the next step is performed.
  7. The DMA transfer process is as follows:
    - a) If the interrupt is enabled (`CH_CTRLx.INT_EN = 1`), and the block completion interrupt is unmasked (`MASK_BLOCK[x] = 1'b1`, where  $x$  is the channel number), the hardware sets the block completion interrupt upon completion of the block transfer. It then stops running until the block completion interrupt is cleared by the software. If the next block is the last block in the DMA transfer, the block completion ISR (interrupt service routine) should clear the source reload register `CH_CFGLx.RELOAD_SRC`. This puts the DMA on row 1, as shown in Table 12-1. If the next block is not the last block of the DMA transfer, then the source reload register should remain enabled to keep the DMA in line 3, as shown in Table 12-1.
    - b) If the interrupt is disabled (`CH_CTRLx.INT_EN = 0`) or the block completion interrupt is masked (`MASK_BLOCK [x] = 1'b0`, where  $x$  is the channel number), then the hardware does

not stop until it detects the write block transfer completion interrupt clears the register, instead it starts the next block transfer immediately. In this case, the software must clear the source reload register CH\_CFGLx.RELOAD\_SRC before the last block of the DMA transfer is completed, thereby putting the DMA in line 1 of Table 12-1.

#### 12.2.9.4 Disable channels until transfer completes

Under normal operation, the software enables the channel by writing 1 to the channel enable register CH\_EN, and the hardware disables the channel by clearing CH\_EN upon completion of the transfer. The recommended method for software to disable a channel without losing data is to use a combination of the CH\_SUSP bit and the FIFO\_EMPTY bit in the channel configuration register (CH\_CFGLx).

1. If the software wishes to disable the channel before the DMA transfer is complete, then it can set the CH\_CFGLx.CH\_SUSP bit to tell the DMA to stop all transfers from the source peripheral. Therefore, the channel FIFO cannot receive new data.
2. The software may poll the CH\_CFGLx.FIFO\_EMPTY bit until it indicates that the channel FIFO is empty.
3. Once the channel FIFO is empty, the CH\_EN bit can be cleared by the software.

When CH\_CTRLx.SRC\_TR\_WIDTH < CH\_CTRLx.DST\_TR\_WIDTH and the CH\_CFGLx.CH\_SUSP bit is high, CH\_CFGLx.FIFO\_EMPTY is set once the data in the FIFO cannot form the unit length of CH\_CTRLx.DST\_TR\_WIDTH. However, there may still be data in the channel FIFO, but not enough to form a single transmission of CH\_CTRLx.DST\_TR\_WIDTH. In this case, the remaining data in the channel FIFO is not transferred to the target peripheral once the channel is disabled.

Allows the suspended state of the channel to be released by writing 0 to the CH\_CFGLx.CH\_SUSP register. The DMA transfer is done in the normal manner.

#### Abnormal transmission aborted

A DMA transmission may be abruptly terminated by software by clearing the channel enable bit CH\_EN. It cannot be assumed that the channel is disabled immediately after setting CH\_EN. The CH\_EN bit is cleared on the AHB slave interface. Considering that this is considered a request to disable the channel, you must confirm that the channel is disabled by reading back CH\_EN to 0. The case where the channel is not disabled after the channel disabling request is that the source or target receives a split or retry response. The DMA must continue to reattempt the transmission to the system HADDR that originally received the split or retry response until an OKAY response is returned, otherwise the AMBA protocol is violated.

The software can abruptly terminate all channels by clearing the global enable bit in the DMA configuration register (DMA\_EN). Similarly, it cannot be assumed that all channels are disabled immediately after clearing DMA\_EN[0]. DMA\_EN[0] is cleared on the AHB slave interface. Consider that this is treated as a request to disable all channels. You must confirm that all channels are disabled by reading back CH\_EN to 0.

If the channel enable bit is cleared when there is data in the channel FIFO, the data is not sent to the target peripheral and does not exist when the channel is re-enabled. For read-sensitive source peripherals, such as source FIFOs, these data are thus lost. When the source is not a read sensitive device, such as memory, it may be acceptable to disable the channel without waiting for the channel FIFO to clear, because data can be obtained from the source peripheral upon request and is not lost.

If the channel is disabled by the software, there is no guarantee that an active single or burst transaction will receive an acknowledgement.

It is not allowed to disable the channel by software before completing the transfer. Clearing the CH\_EN bit before the channel is suspended may violate the AHB protocol.

## 13. Interrupts and events

### 13.1 Nested vectored interrupt controller (NVIC)

The interface between nested vector interrupt controller (NVIC) and processor core is closely connected, which can realize low latency interrupt processing and efficiently handle late interrupts.

The nested vector interrupt controller manages interrupts such as kernel exceptions. Please refer to the Cortex-M4F Programming Manual for more instructions on exceptions and NVIC programming.

#### 13.1.1 Main features

- 86 maskable interrupt channels (excluding 16 Cortex® -M4F interrupt line);
- 8 programmable priority levels (3-bit interrupt priority is used);
- Low latency exception and interrupt handling;
- Power management control;
- Implementation of System Control Register;

#### 13.1.2 SysTick Calibration Value Register

The system tick calibration value is fixed at 9000, and when the system tick clock is set to 9MHz, a 1ms time reference is generated.

#### 13.1.3 Break and Exception Vector Table

| Vector numbering | Priority | Type of priority | Pin name                                                              | Address     | Description                                               |

## 13.2 External Extended Interrupt/Event Controller (EXTI)

The extended interrupt and event controller manages CPU and system wake-up functions through configurable lines and direct input lines, and outputs the following request signals:

- Event request, event input sent to the CPU
- The wake-up request is sent to the power consumption management control module

EXTI wake-up requests allow the system to wake up from stop mode, and event requests can also be used in run mode.

EXTI allows the management of up to 31 configurable and direct input lines (22 configurable and 9 direct input lines).

There are 31 edge detectors that can generate event/interrupt requests. There are 22 configurable lines, and each input line can be independently configured with an input trigger mode (rising edge or

falling edge or double edge trigger). 31 configurable lines and direct input lines, each input line can be shielded independently. The suspend register holds the interrupt request for the configurable line.

### 13.2.1 Main features

The main features of the EXTI controller are as follows:

- Low power mode can be awakened via GPIO and designated modules (e.g. PVD/RTC, etc.)
- Configurable line
  - Optional valid trigger edge (rising/falling edge)
  - Interrupt pending status bits
  - Independent interrupt and event masking bits
  - SW trigger possibility
- Direct input line
  - Fixed rising edge active trigger
  - No interrupt suspend flag bit
  - No independent interrupt and event mask bits
  - No SW trigger possibility

### 13.2.2 Wake-up event management

This product can handle external or internal events to wake up the kernel (WFE). The wake-up event can be generated by the following configuration:

- An interrupt is enabled in the control register of the peripheral, but not in the NVIC, while the SEVONPEND bit is enabled in the system control register of the Cortex-M4F. When the CPU recovers from the WFE, it is necessary to clear the interrupt suspend bit of the corresponding peripheral and the peripheral NVIC interrupt channel suspend bit (in the NVIC interrupt clear suspend register).
- Configure an external or internal EXTI line to event mode. When the CPU recovers from WFE, because the suspension bit of the corresponding event line is not set, it is not necessary to clear the interrupt suspension bit of the corresponding peripheral or the NVIC interrupt channel suspension bit.

### 13.2.3 Function description

To generate an interrupt, the interrupt line must be configured and enabled first. The 22 configurable lines set 2 trigger registers according to the required edge detection, while writing '1' to the corresponding bit of the interrupt mask register allows interrupt requests. When the expected edge occurs on the external interrupt line, an interrupt request will be generated, and the corresponding suspend bit will be set '1' accordingly. The interrupt request will be cleared by writing '1' in the corresponding bit of the suspend register. If you need to generate an event, you must first configure and enable the event line. According to the required edge detection, the event request is allowed by setting 2 trigger registers while writing '1' to the corresponding bit of the event mask register. When a desired edge occurs on the event line, an event request pulse will be generated, and the corresponding suspend bit will not be set to '1'. An interrupt/event request can also be generated by software by writing '1' in the software interrupt event register.

### 13.2.3.1 EXTI block diagram

### 13.2.3.2 Hardware interrupt selection

- Configure the mask bit of the interrupt line (EXTI\_IMRx (x = 1, 2))
- Configuring trigger select bits (EXTI\_RTSTR and EXTI\_FTSTR) for the selected interrupt line;

### 13.2.3.3 Hardware event selection

- Configure the mask bit of the event line (EXTI\_EMRx (x = 1, 2))
- Configure the trigger select bits of the event line (EXTI\_RTSTR and EXTI\_FTSTR)

### 13.2.3.4 Selection of Software Interrupts/Events

- Configure interrupt/event line masking bits (EXTI\_IMRx, EXTI\_EMRx; (x = 1, 2))
- Set the request bit of the software interrupt register (EXTI\_SWIER)

### 13.2.4 External interrupt/event line mapping

86 general purpose I/O ports are connected to 16 external interrupt/event lines in the manner shown below:

Note: To configure external interrupts/events on the GPIO line via SYSCFG\_EXTICRx, the SYSCFG clock must be enabled first.

Table13-1 EXTI lines connections

| EXTI | Line source      | Line Type         |

## 14. Analog-to-digital converters (ADC)

### 14.1 Introduction

A 12-bit ADC is an analog-to-digital converter using successive approximation. It has 20 multiplexed channels and can convert analog signals from multiple external channels and multiple internal channels. The analog watchdog allows the application to detect whether the input voltage exceeds the user-set high and low threshold. The A/D conversion of the individual channels may be configured in a single, continuous, scanning, or intermittent conversion mode. The results of the ADC conversion can be stored in a 16-bit data register in a left-aligned or right-aligned manner.

### 14.2 Main Features

- High Performance:
  - Configurable 12-, 10-, 8-and 6-bit resolutions
  - Maximum ADC sampling rate: 4 Msps
  - Self-calibration
  - Programmable sampling time
  - The data register allows configurable data alignment
  - Support DMA requests for regular channel data conversion
  - Dual ADC Mode
  - Configurable single-ended or differential inputs
- Oversampler
  - 16 bits Data register
  - Oversampling rate 2-256 adjustable
  - Programmable data shift up to 8 bits
- Data preprocessing
  - Gain compensation
  - Offset compensation
- Dynamic low power consumption characteristics:
  - Automatic delay transition mode: prevents overflow when operating with low frequency PCLK
- Analog input channel:
  - ADC1 connects 14 external channels, 5 internal channels and 1 internal VSSA channel
  - ADC2 connects 16 external channels, 3 internal channels and 1 internal VSSA channel
  - ADC3 connects 15 external channels, 4 internal channels and 1 internal VSSA channel
- Start conversion method:
  - By software
  - Hardware triggering
- Conversion mode:
  - Single-shot mode, which converts the selected input channel once per trigger;
  - Scan mode, which can scan a series of channels;
  - A continuous mode that continuously switches the selected input channel;

- Discontinuous mode, each trigger continuously converts sub-sequence channels, and multiple triggers until all channels are converted
- Synchronous mode (for devices with two ADCs).
- Analog watchdog
- Generation of interrupts:
  - End of Sampling
  - Transition End (Rule/Injection Channel)
  - End of rule sequence or injection sequence conversion
  - Simulated Watchdog 1, 2, 3 events
- ADC input range (select external reference voltage):  $V_{REF-} \leq V_{IN} \leq V_{REF+}$

## 14.3 Function description

### 14.3.1 ADC module block diagram

Figure 14-1 ADC module block diagram

### 14.3.2 ADC1/2/3 connection relationship

The external channels of ADC1, ADC2, and ADC3 share some GPIO (channel configuration is set via ADC\_SQRx or ADC\_JSQR), as shown in the figure below.

Figure 14-2 ADC1 channel connection relationship

Figure 14-3 ADC2 channel connection relationship

Figure 14-4 ADC3 channel connection relationship

### 14.3.3 ADC1/2/3 use restrictions

1. Single ADC and dual ADC modes: Discontinuous mode (DISCEN), which does not support injection interrupt rules.
2. Single ADC and dual ADC modes: Automatic delay conversion mode (AUTDLY), which does not support injection interrupt rules.
3. Single ADC and Dual ADC Modes: Automatic Injection (JAUTO) does not support Automatic Delay Conversion Mode (AUTDLY) mode
4. Single ADC and Dual ADC modes: Rule triggers during injection are ignored.
5. Single ADC and Dual ADC Modes: For single conversion mode, the software must set the rule sequence length to 0.
6. Dual ADC mode (ADC3 does not have dual ADC mode):
  - a) The JEXTEN/JEXTSEL/EXTEN/EXTSEL/JADSTART/ADSTART of the Slave ADC must remain reset
  - b) Injection break rules are not supported when DUAL = 7, 8, 9
  - c) When DUAL = 8, the sampling time can only be selected as 2.5, 3.5 and 6.5 ADC clock cycles, and other sampling times cannot be configured.

### 14.3.4 Single-ended and differential input channels

The ADC channel can be configured as a single-ended input or a differential input, configured by DIFSEL in the ADC\_DIFSEL register. When DIFSEL [x] (x = 0-19) is 1, the channel that is selected to be converted is differential input mode, otherwise it is single-ended input mode.

Must be configured when the ADC is disabled (ADEN = 0). Note that the single-ended channel corresponding to DIFSEL is always kept at 0.

In single-ended mode, the analog voltage of channel i (i = 0-19) is the difference between ADCy\_INx (VINP [i]) and VREF-.

In differential mode, the analog voltage of channel i (i = 0-19) is the voltage difference between ADCy\_INx (VINP [i]) and ADCy\_INx+1 (VINN [i]).

In differential mode, the input voltage ranges from VREF- to VREF +, reaching a full scale of 2xVREF +. When VINP [i] is equal to VREF - and VINN [i] is equal to VREF +, the maximum negative input differential voltage (VREF -) corresponds to 0x000 output. When VINP [i] is equal to VREF + and VINN [i] is equal to VREF -, the maximum positive input differential voltage (VREF +) corresponds to the 0xFFFF output. When VINP [i] and VINN [i] are connected together, the zero input differential voltage corresponds to the 0x800 output.

The ADC sensitivity in differential mode is twice less than in single-ended mode. Internal channels, such as VSENSE and VREFINT, are in single-ended mode only.

For a complete description of each ADC input channel connection, see the relevant section description.

#### **Warning:**

When channel "i" is configured in differential input mode, its negative input voltage VINN [i] is already connected to another channel, so this channel is no longer available for single-ended mode or differential mode, and conversion must not be configured. ADC1/ADC2/ADC3 share some channels: this

may cause a channel on another ADC to be unavailable. The only exception is when the master ADC and the slave ADC are operating in crossover mode.

#### **14.3.5 ADC calibration**

The ADC has a calibration function, which can be enabled by users through software. During calibration, the ADC calculates a calibration factor for use inside the ADC (lost after the ADC is powered down). The application cannot use the ADC module during the ADC calibration and until the calibration is complete. Before using ADC conversion, users are advised to perform calibration operations. Calibration is used to eliminate offset errors and mismatch errors between chips due to process and temperature changes.

##### **14.3.5.1 ADC software calibration**

The software sets `ADCAL = 1` to start calibration. The calibration can only be started when the ADC is not turned on (`ADEN = 0`), and only supports selecting the system clock as the clock of the ADC. The calibration clock frequency is 1/4 of the normal conversion clock frequency. When the calibration is complete, the `ADCAL` is cleared by the hardware.

When the operating conditions of the ADC change (`VCC` change is the main factor of offset error and mismatch error, followed by temperature change), it is recommended to recalibrate.

The number of repetitions of the calibration process is configured by setting `CALNUM [2: 0]` in the `ADC_CFGR2` register, and the results are averaged to get more accurate calibration results. (Note: `CALNUM` cannot be 0 when the calibration average result is compensated to AD conversion)

The internal calibration register can be reset by setting the `RSTCAL` of `ADC_CR`, which is set to 0 by a hardware clear. This bit is cleared after the calibration register is initialized (i.e., after `RSTCAL` is set to 1).

Software procedure to calibrate the ADC:

1. Confirm `ADEN = 0`
2. Set `RSTCAL` (this step is optional);
3. Set the number of calibrations `CALNUM` (this step is optional);
4. Set `ADCAL = 1`
5. The ADC internally automatically delays 192 ADC CLKs to wait for the ADC to stabilize;
6. Wait until `ADCAL = 0`

Figure 14-5 ADC Calibration

### 14.3.6 ADC on-off control

The ADEN of the ADC\_CR register is the enable switch of the ADC module. In order to save power, when ADEN is 0, the ADC analog circuit will enter power-down mode.

Note: After the ADEN bit is set to 1, the hardware waits for a delay ( $t_{STAB}$ ) of not less than 3 us before converting.

By clearing the ADEN bit, the transition can be stopped and the ADC state can be reset, and the ADC analog circuit can be put into power down mode.

### 14.3.7 Limits on Write ADC Control Bits

Only when the ADC is disabled ( $ADEN = 0$ ) and there is no calibration ( $ADCAL = 0$ ), the software writes RCC to enable the ADC clock (see RCC section), the software can be configured:

- CALNUM for ADC\_CFGR2
- RSTCAL, ADCAL, and ADEN in the ADC\_CR register.
- ADC\_CALFACT

For all registers except the above registers:

- The software is only allowed to write these control bits when the ADC does not have ongoing rules and injection translations.

For the ADC\_CCR register, software is allowed to write these control bits only when the ADC is disabled ( $ADEN = 0$ ).

Note: If the ADC registers are not configured as described in this section, the ADC behavior may be in an unknown state. To recover from this situation, ADC must be disabled ( $ADEN$  cleared).

### 14.3.8 ADC clock

The ADC CLK and PCLK2 (APB2 clock) supplied by the clock controller are synchronized. The RCC controller (CLK controller) provides a dedicated programmable prescaler for the ADC clock.

### 14.3.9 ADC channel selection

ADC1 has 14 external channels, 5 internal channels and 1 internal VSSA channel, where the internal channels are:

- ADC1\_CH15 connects OPA1

- ADC1\_CH16 connects temperature sensor VSENSE,
- ADC1\_CH17 connects VCC/3,
- ADC1\_CH18 connects VREFINT,
- ADC1\_CH19 connects DAC1.

ADC2 has 16 external channels, 3 internal channels and 1 internal VSSA channel, where the internal channels are:

- ADC2\_CH17 connects OPA2,
- ADC2\_CH18 connects OPA3,
- ADC2\_CH19 is connected to DAC2.

ADC3 has 15 external channels, 4 internal channels and 1 internal VSSA channel, where the internal channels are:

- ADC3\_CH16 connects OPA3,
- ADC3\_CH17 connects VCC/3,
- ADC3\_CH18 connects VREFINT,
- ADC3\_CH19 is connected to DAC1.

ADCchannel selection can be configured through ADC\_SQRx or ADC\_JSQR. The correspondence between configuration values and channels is described in the above chapter.

ADC divides conversions into two groups: rule conversions and injection conversions. Each group contains a sequence of transformations that can be completed on any channel in any order. For example, the sequence may be converted in the following order: ADC\_IN3, ADC\_IN8, ADC\_IN2, ADC\_IN2, ADC\_IN0, ADC\_IN2, ADC\_IN2, ADC\_IN15. All channels can be converted by injection or regular channel group.

- A rule transformation group consists of up to 16 transformations. The regular channel of the conversion sequence and its conversion order are selected in the ADC\_SQRx register. The sequence length in the rule transformation group must be written L [3: 0].
- An injection conversion group consists of a maximum of 4 conversions. The injection channel and its conversion order are selected in the ADC\_JSQR register. The sequence length in the injection translation group must be written to the JL [1: 0] bit. (Note: Unlike regular conversion sequences, if the length of JL [1: 0] is less than 4, the sequence order of the conversion starts from (4-JL).)

#### 14.3.10 Forced stop of ADC

The software sets ADSTP = 1 in the ADC\_CR register to stop the current conversion and let the ADC enter the idle state to prepare for the next conversion.

When ADSTP is set to 1 by the software, any current transition is aborted and the transition result is discarded (the ADC\_DR register is not updated with the current transition value). Once the conversion process is finished, ADSTP is cleared by hardware.

#### 14.3.11 Dynamic low power consumption characteristics

##### 14.3.11.1 Automatic Delay Conversion Mode (AUTDLY)

The automatic delay conversion mode can be used to simplify software and optimize application performance when running at low speeds. Of course, ADC overflow is not easy to occur in this mode. This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

Automatic delay conversion (AUTDLY) mode means that after one conversion of a regular channel, you need to wait for the CPU/DMA to read away the data in the data register before starting the sampling conversion of the next channel. If the CPU/DMA does not read the last converted data, the whole sampling conversion cycle will not switch to the next channel, but will remain in a waiting state until the last converted data is read and then the conversion will continue. If a regular channel trigger event occurs during AUTDLY, the trigger event is ignored.

The AUTDLY mechanism supports all conversion modes of the regular channel. When the AUTDLY flag bit is enabled, it indicates that the ADC conversion cycle needs to wait for the data register to be read away before it can be carried out.

Note: AUTDLY mode does not support injection-triggered interrupt rule transformations.

### 14.3.12 Conversion modes

#### 14.3.12.1 Single conversion mode

In the single conversion mode, the ADC performs a conversion on a single channel, which can be run in the rule group and the injection group. The SQ1 [4: 0] bit specifies the single conversion channel of the ADC rule group, and the application should keep L as 0; When injecting a single transition channel, the application should keep JL at 0. (Note: Unlike regular transition sequences, if the length of JL [1: 0] is less than 4, the sequence order of transitions starts from (4-JL).) The JSQ4 [4: 0] bit of the ADC\_JSQR register configures the injection group single transition channel.

When the ADEN bit is 1 and CONT, SCAN, and DISCEN/JDISCEN are all 0, the ADC will sample and convert a channel once the corresponding external trigger occurs. (Note: Single-shot mode and continuous mode cannot be enabled at the same time, that is, CONT is 0 in single-shot mode.)

- If a regular channel was converted:

When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

- The conversion data is stored in the 16-bit ADC\_DR register

- After the conversion is completed, the EOC (conversion end) flag is set

- If EOCIE is set, interrupt is generated.

- If an injected channel is converted:

When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

- Conversion data is stored in a 16-bit ADC\_JDRx (x = 1-4) register

- JEOC (Injection Conversion End) flag is set after the conversion is completed

- If JEOCIE bit is set, an interrupt is generated.

After the rule sequence is complete:

- Set the EOS (End of Rule Sequence) flag
- If the EOSIE bit is set, an interrupt is generated

After completion of the injection sequence:

- Set the JEOS (End of Injection Sequence) flag
- If the JEOSIE bit is set, an interrupt is generated

### 14.3.12.2 Continuous conversion mode

In the continuous conversion mode, the ADC continuously converts the selected channel, and this mode can be run in the rule group. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

- Regular Channel Group: The successively converted channels are set by the SQ1 [4: 0] bit.
- Injection channel group: only a single conversion is performed, and the converted channel SQx [4: 0] (x = 1-4) is set. Note: Unlike regular transformation sequences, if the length of JL [1: 0] is less than 4, the sequence order of the transformation starts from (4-JL)

When the ADEN bit is 1 and the CONT is 1, the ADC samples and converts the selected channel once the corresponding external trigger occurs.

- If a regular channel was converted:
  - The conversion data is stored in the 16-bit ADC\_DR register
  - After the conversion is completed, the EOC (conversion end) flag is set
  - If EOCIE is set, interrupt is generated.
- If an injected channel is converted:
  - Conversion data is stored in a 16-bit ADC\_JDRx (x = 1-4) register
  - JEOC (Injection Conversion End) flag is set after the conversion is completed
  - If JEOCIE bit is set, an interrupt is generated.

After the sequence of conversions is complete:

- Set the EOS (End of Sequence) flag
- If the EOSIE bit is set, an interrupt is generated

The new sequence is then immediately restarted, and the ADC continuously repeats the switching sequence.

After completion of the injection sequence:

- Set the JEOS (End of Injection Sequence) flag
- If the JEOSIE bit is set, an interrupt is generated

Note: You cannot enable intermittent conversion mode and continuous mode at the same time: it is forbidden to set JDISCEN/DISCEN = 1 and CONT = 1 at the same time. The injected channel does not support continuous conversion mode.

### 14.3.12.3 Scan mode

When scanning conversion mode, the ADC continuously converts all channels of a selected sequence. This mode can be run in the rule group and the injection group. ADC\_SQRx specifies a regular sequence length and all conversion channels, where the L [3: 0] bit specifies the sequence length. The ADC\_JSQR register specifies an injection group sequence length and all conversion channels, where the JL [1: 0] bit specifies the sequence length (Note: Unlike regular conversion sequences, if the length of JL [1: 0] is less than 4, the sequence order of conversion starts from (4-JL)). When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

When the ADEN bit is 1 and the SCAN is 1, the ADC samples and converts a sequence once the corresponding external trigger occurs.

- If a sequence of rules is converted:

-The conversion data is stored in the 16-bit ADC\_DR register

The EOC (End of Conversion) flag is set after the completion of each channel conversion, and the EOS flag is set after the completion of the entire sequence conversion.

-If EOCIE is set, an interrupt is generated, if EOSIE is set, an interrupt is generated.

■ If an injection sequence is converted:

-Conversion data is stored in a 16-bit ADC\_JDRx (x = 1-4) register

JEOC (End of Injection Transition) flag is set after each channel transition is completed, and JEOS flag is set after the entire sequence transition is completed.

-If JEOCIE bit is set, an interrupt is generated. An interrupt is generated if JEOSIE is set.

#### 14.3.12.4 Discontinuous mode

In the intermittent conversion mode, the ADC divides the selected sequence into sub-sequences (sequence length 1-8), and completes the whole sequence conversion by externally triggering the sub-sequences many times. This mode can be run in the rule group and the injection group. DISCNUM specifies the regular channel subsequence length, and ADC\_SQRx (x = 1-4) specifies all conversion channels of a regular sequence, where L [3: 0] bits specify the sequence length. The ADC\_JSQR register specifies all translation channels of an injection group sequence, where the JL [1: 0] bit specifies the sequence length (Note: Unlike regular translation sequences, if the length of JL [1: 0] is less than 4, the sequence order of translations starts from (4-JL)). When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

Note: The subsequence of the injection channel group is 1. In this mode, DISCEN and JDISCEN are prohibited from being enabled at the same time

■ Regular group

An external trigger signal initiates the ADC\_SQRx (x = 1-4) description channel n (n ≤ 8) transitions until all transitions in this sequence are complete. The total sequence length is defined by L [3: 0].

For example:

n = 3, transformed channels = 0, 1, 2, 3, 6, 7, 9, 10

First trigger: The sequence of transitions is 0, 1, 2, and an EOC event is generated at the end of each channel transition.

Second trigger: The sequence of transitions is 3, 6, 7, and an EOC event is generated at the end of each channel transition.

Third trigger: The sequence of transitions is 9 and 10, and the end of each channel transition generates an EOC event. The end of the sequence produces an EOS event.

Fourth trigger: Transition sequence 0, 1, 2, EOC event is generated at the end of each channel transition.

Note: When a rule group is converted in discontinuous mode, the conversion sequence does not automatically start from the beginning. When all subgroups have been converted, the next trigger initiates the conversion of the first subgroup. In the above example, the fourth trigger re-switches channels 0, 1 and 2 of the first subset.

■ Injected group

An external trigger signal initiates 1 transition of the ADC\_JSQR description channel until all transitions in the sequence are completed. Total sequence length JL [1: 0] bit definition.

Examples include:

$n = 1$ , channel being converted = 1, 2, 3

First trigger: Channel 1 is converted, and the end of each channel conversion generates a JEOC event.

Second trigger: Channel 2 is converted, and the end of each channel conversion produces a JEOC event.

Third trigger: Channel 3 is converted, and the end of each channel conversion produces a JEOC event. The end of the sequence produces a JEOS event.

Fourth trigger: Channel 1 is converted, and the end of each channel conversion generates a JEOC event.

Notes:

1 When all injection channel transitions are completed, the next trigger starts the transition of the first injection channel. In the above example, the fourth trigger re-switches the first injection channel 1.

2 Automatic injection and intermittent modes cannot be used simultaneously.

3 You must avoid setting discontinuous mode for rules and injection groups at the same time. The discontinuous mode can only act on one set of transitions.

#### 14.3.13 Injected channel management

The injection channel external trigger has a higher priority than the regular channel external trigger, that is, the injection channel external trigger can interrupt the ongoing regular channel transition. The injection channel is interrupted in two ways: triggered injection and automatic injection.

##### 14.3.13.1 Triggered injection

In the process of executing a rule sequence, the ADC detects an external trigger of the injection channel, and interrupts the channel that the current rule sequence is converting, and starts to execute the injection sequence conversion. When all the injection sequences are converted, the ADC restores the interrupted rule channel and completes the rule sequence conversion.

ADC\_SQRx ( $x = 1-4$ ) specifies a regular sequence of all conversion channels, where L [3: 0] bits specify the sequence length. The ADC\_JSQR register specifies all transition channels of an injection group sequence, where the JL [1: 0] bit specifies the sequence length. Note: Unlike regular translation sequences, if the length of JL [1: 0] is less than 4, the sequence order of the translation starts from (4-JL).

Note: JAUTO must be 0 when injection is triggered. A rule trigger event occurs during an injection channel transition, which transforms after the injection channel is completed, that is, starts the rule sequence from scratch instead of resuming the interrupted rule channel. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

(Note: Discontinuous mode does not support trigger injection; AUTDLY function is not supported when trigger injection; When rule trigger and injection trigger occur simultaneously, rule trigger is discarded and only injection trigger is executed; rule trigger during injection is ignored.)

Figure 14-6 ADC Trigger Injection (Scan Mode)

#### 14.3.13.2 Auto-injection

In automatic injection mode, the ADC automatically performs injection sequence conversion after completing a regular sequence. JAUTO enables the auto-injection mode bit. ADC\_SQRx (x = 1-4) specifies a regular sequence of all conversion channels, where L [3: 0] bits specify the sequence length. The ADC\_JSQR register specifies all transition channels of an injection group sequence, where the JL [1: 0] bit specifies the sequence length. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

For automatic injection in non-oversampling mode, after the injection sequence is finished, JEOS and EOS are set.

For automatic injection in oversampling mode, after the end of the regular sequence, EOS is set, and after the end of the injection sequence, JEOS is set.

(Note that this mode must disable the external trigger of the injection channel; you can't use auto-injection and intermittent modes at the same time; auto-injection does not support AUTDLY mode)

Figure 14-7 ADC automatic injection (CONT + SCAN + JAUTO)

### 14.3.14 Analog watchdog

Three AWD analog watchdogs monitor whether the ADC channel remains within the configured voltage range (window)

Figure 14-8 Simulated watchdog protection area

#### 14.3.14.1 AWDx flags and interrupts

Interrupts can be enabled for each of the 3 analog watchdogs by setting AWDxIE (x = 1, 2, 3) in the ADC\_IER register. The AWDx (x = 1, 2, 3) flag is cleared by the software writing 1. The ADC conversion results were compared to low threshold, high threshold before data alignment.

#### 14.3.14.2 Analog Watchdog 1 Description

Enable AWD simulation watchdog 1 via the set JAWD1EN/AWD1EN bit. This watchdog monitors whether a selected injection/rule channel or all enabled injection and rule channels remain within the configured voltage range (window).

The following table shows how the ADC\_CFGR register should be configured to enable analog watchdogs on one or more channels.

Table 14-1 Analog watchdog channel selection

| Channels to be guarded by analogwatchdog | AWD1SGL bit | AWD1EN bit | JAWD1EN bit |
|------------------------------------------|-------------|------------|-------------|
| None                                     | x           | 0          | 0           |
| All injected channels                    | 0           | 0          | 1           |
| All regular channels                     | 0           | 1          | 0           |
| All rules and injection channels         | 0           | 1          | 1           |

|                               |   |   |   |
|-------------------------------|---|---|---|
| Single injection channel      | 1 | 0 | 1 |
| Single regular channel        | 1 | 1 | 0 |
| Single rule/injection channel | 1 | 1 | 1 |

- When AWD1SGL is selected by AWD1CH [4: 0], the watchdog protects the channel, and the protected channel shall be converted in a regular or injection sequence.

If the analog voltage converted by the ADC is lower than the low threshold or higher than the high threshold, the AWD1 analog watchdog status bit is set. These thresholds are written in bits HT1 [11: 0] and LT1 [11: 0] of the ADC\_TR1 register of the analog watchdog 1. When transforming data with a resolution less than 12 bits (according to bit RES [1: 0]), the LSB of the threshold must be kept at 0 because internal comparisons are always performed on the full 12-bit raw transformed data (left-aligned).

The following table describes how the comparison is performed for all possible resolutions of the simulated watchdog 1.

Table 14-2 Simulated Watchdog 1 Comparison

| Resolution (RES [1: 0]) | Analog watchdog comparison between:  |                             | Description                                             |
|-------------------------|--------------------------------------|-----------------------------|---------------------------------------------------------|
|                         | Original transformation left aligned | Thresholds                  |                                                         |
| 00: 12 bit              | DATA [11: 0]                         | LT1 [11: 0] and HT1 [11: 0] | -                                                       |
| 01: 10bit               | DATA [11: 2], 00                     | LT1 [11: 0] and HT1 [11: 0] | The user must configure LT1 [1: 0] and HT1 [1: 0] to 00 |
| 10: 8 bit               | DATA [11: 4], 0000                   | LT1 [11: 0] and HT1 [11: 0] | The user must configure LT1 [3: 0] and HT1 [3: 0] to 00 |
| 11: 6bit                | DATA [11: 6], 000000                 | LT1 [11: 0] and HT1 [11: 0] | The user must configure LT1 [5: 0] and HT1 [5: 0] to 00 |

- For more details on analog watchdog comparisons, see the "Gain Compensation" section.

#### 14.3.14.3 Analog Watchdog Filter for Watchdog 1

When the ADC is configured with only one input channel (multiple channels are not allowed to be selected in scan mode), the valid ADC conversion data interval can be configured through the ADC\_TR1 register:

- When the conversion result exceeds the configured high/low threshold, but is within the interval defined in ADC\_TR1, a DMA request is generated for each conversion result (if DMA is enabled).
- Otherwise, no DMA request is issued (i.e., multiple consecutive transition results exceed the configured threshold and exceed the interval, and the transition result exceeding the interval does not produce a DMA request (if DMA is enabled)). The RDATA register is updated with each conversion. If the data is out of range several times higher than the value specified in the AWDFILT bit of ADC\_TR1, the AWDx flag is set and the corresponding interrupt is generated.

#### 14.3.14.4 Description of Watchdogs 2 and 3

The 2nd and 3rd analog watchdogs are more flexible and can protect several selected channels by programming the corresponding bits in AWDxCH [19: 0] (x = 2, 3). When any bit of AWDxCH [19: 0] (x = 2, 3) is set, the corresponding watchdog is enabled. They are limited to a resolution of 8 bits, and only a threshold of 8 MSBs can be programmed as HTx [7: 0] and LTx [7: 0] (x = 2-3). The following table describes how the comparison is performed for all possible resolutions.

Table 14-3 Simulated Watchdog 2 and 3 Comparison

| Resolution (RES [1: 0]) | Analog watchdog comparison between:  |                           | Description                                             |
|-------------------------|--------------------------------------|---------------------------|---------------------------------------------------------|
|                         | Original transformation left aligned | Thresholds                |                                                         |
| 00: 12 bit              | DATA [11: 4]                         | LTx [7: 0] and HTx [7: 0] | Data [3: 0] is not relevant to the comparison           |
| 01: 10 bit              | DATA [11: 4]                         | LTx [7: 0] and HTx [7: 0] | Data [3: 2] are not relevant for comparison             |
| 10: 8 bit               | DATA [11: 4]                         | LTx [7: 0] and HTx [7: 0] | -                                                       |
| 11: 6 bit               | DATA [11: 6], 00                     | LTx [7: 0] and HTx [7: 0] | The user must configure LTx [1: 0] and HTx [1: 0] to 00 |

#### 14.3.14.5 ADCy\_AWDx\_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADCy\_AWDx\_OUT (y = 1, 2, 3; x = 1, 2, 3), which is directly connected to the ETR input (externally triggered) of some on-chip timers. Refer to the on-chip timer section to learn how to select the ADCy\_AWDx\_OUT signal as the ETR. ADCy\_AWDx\_OUT is activated when the associated analog watchdog is enabled:

- When the protected transition exceeds the programming threshold, ADCy\_AWDx\_OUT is set.
- ADCy\_AWDx\_OUT resets after the end of the next guard transition within the threshold (remains at 1 if the next analog watchdog channel transition is still outside the programmed threshold).
- When the ADC is disabled (when ADEN = 0 is set), ADCy\_AWDx\_OUT is reset. Note that stopping rules or injected transformations (setting ADSTP = 1) have no effect on the generation of ADCy\_AWDx\_OUT.

Note: The AWDx flag is set by the hardware and reset by the software: the AWDx flag has no effect on the generation of ADCy\_AWDx\_OUT (for example, if the software does not clear AWDx, the AWDx flag remains at 1 and the ADCy\_AWDx\_OUT can be flipped).

Table 14-4 ADCy\_AWDx\_OUT connection relationship

| ADC1_AWDx_OUT |           |           | ADC2_AWDx_OUT |           |            | ADC3_AWDx_OUT |           |            |
|---------------|-----------|-----------|---------------|-----------|------------|---------------|-----------|------------|
| AWD1          | AWD2      | AWD3      | AWD1          | AWD2      | AWD3       | AWD1          | AWD2      | AWD3       |
| tim1_etr5     | tim1_etr6 | tim1_etr7 | tim3_etr8     | tim3_etr9 | tim3_etr10 | tim8_etr8     | tim8_etr9 | tim8_etr10 |
| -             | -         | -         | tim8_etr5     | tim8_etr6 | tim8_etr7  | -             | -         | -          |

#### 14.3.14.6 Analog watchdog with gain and offset compensation

When gain and offset compensation are enabled, the analog watchdog compares thresholds after compensating the data.

Note: When offset compensation is enabled (OFFSETy\_EN in the ADC\_OFRRy register is set to 1), data overflows or underflows can result in false watchdog results. When overflow protection is enabled (with SATEN set to 1 in ADC\_OFRRy), the watchdog provides the correct results. But this prevents the use of signed data format.

#### 14.3.15 Data processing

##### 14.3.15.1 Data alignment

The ALIGN bit in the ADC\_CFGR register is used to select the alignment mode of the data stored after conversion. You can choose left alignment and right alignment. The converted data value has been subtracted from the custom offset in the ADC\_OFRRy register, so the result can be a negative value. The SEXT bit represents the extended sign value.

Special case: When left alignment, except for the resolution of 6 bits, other resolution data are aligned on a half-word basis. At a resolution of 6 bits, the data is aligned on a byte basis.

Note: Left alignment is not supported in oversampling mode. When the ROVSE or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

#### 14.3.15.2 offset

An offset  $y$  ( $y = 1, 2, 3, 4$ ) can be applied to the channel by setting  $OFFSETy\_EN = 1$  in the  $ADC\_OFRy$  register. The application can select the offset channel by bit  $OFFSETy\_CH$  [4: 0] of the  $ADC\_OFRy$  register. In this case, the conversion result is subtracted by the user-defined offset in  $OFFSETy$  [11: 0], and the result may be negative, so the read data is signed and the SEXT bit represents the extended sign value.

Note: offset is not supported in oversampling mode. When the ROVSE or JOVSE bit is set, the value of the  $OFFSETy\_EN$  bit in the  $ADC\_OFRy$  register is ignored (considered a reset).

The following table describes how to perform comparisons for all possible resolutions of offset.

Table 14-5 Offset calculated values vs Data resolution

| Resolution (RES [1: 0]) | Raw conversion result and offset subtraction |                | Result              | Description                                    |
|-------------------------|----------------------------------------------|----------------|---------------------|------------------------------------------------|
|                         | Original conversion result<br>Left alignment | Offset         |                     |                                                |
| 00: 12 bit              | DATA [11: 0]                                 | OFFSET [11: 0] | Signed 12bit number | -                                              |
| 01: 10bit               | {DATA [11: 2], 00}                           | OFFSET [11: 0] | Signed 10bit number | The user must configure OFFSET [1: 0] = 00     |
| 10: 8 bit               | {DATA [11: 4], 0000}                         | OFFSET [11: 0] | Signed 8-bit number | The user must configure OFFSET [3: 0] = 0000   |
| 11: 6bit                | {DATA [11: 6], 000000}                       | OFFSET [11: 0] | Signed 6-bit number | The user must configure OFFSET [5: 0] = 000000 |

When reading data from  $ADC\_DR$  (regular channel) or  $ADC\_JDRy$  (injection channel,  $y = 1, 2, 3, 4$ ) corresponding to channel "i":

- If one of the offsets of the corresponding channel is enabled (bit  $OFFSETy\_EN = 1$ ), the data is read signed.
- If none of the four offsets for this channel are enabled, the read data is unsigned.

The following figure shows signed and unsigned data alignment.

Figure 14-9 right-aligned (offset not enabled, unsigned number)

Figure 14-10 right aligned (offset enabled, signed number)

Figure 14-11 left aligned (offset not enabled, unsigned number)

Figure 14-12 left aligned (offset enabled, signed number)

#### 14.3.15.3 Gain compensation

When the ADC\_CFGR2 register GCOMP bit is set, all converted data is gain compensated. After each conversion, the data will be calculated using the following formula.

$$\text{DATA} = \text{DATA (adc result)} \times (\text{GCOMPCOEFF}) / 4096$$

Since GCOMPCOEFF ranges from 0-16383, the actual gain compensation factor ranges from 0-3.999756.

The calculated LSB - 1 values are rounded and the error is minimized before the resulting data is stored in the RDATA or JDATAx register.

Gain compensation is also effective for oversampling. When gain compensation is used in the oversampling mode, the gain calculation is performed after the accumulation and right shift operation to minimize power consumption (the gain calculation is only done once, not every transition).

#### 14.3.15.4 Offset compensation

When the offset is enabled while the SATEN bit is set in the ADC\_OFRy register, the data is unsigned. All offset data is saturated at 0x000 (at 12-bit resolution). When the OFFSETPOS bit is set, the offset direction is positive and the data is saturated at 0xFFF (at 12-bit resolution). In 8-bit resolution, the data is saturated at 0x00 and 0xFF, respectively.

After offset and gain compensation, an analog watchdog comparison is performed on the unsigned number. For proper watchdog operation, offset-compensated data must be in unsigned format (the SATEN bit in the ADC\_OFRy register is set to 1).

#### 14.3.16 Oversampler

The oversampling unit performs data preprocessing to offload the CPU computation load. It can handle multiple conversions and average them into a single data (increasing the data width up to 16 bits).

The oversampler provides the following formula, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

The oversampler allows the following functions to be performed by hardware: averaging, reducing data rate, improving signal-to-noise ratio, basic filtering.

The oversampling rate N is defined by the OVSr [2: 0] bit in the ADC\_CFGR2 register and can be adjusted in the range of 2x to 256x. The division coefficient M is implemented by a right shift, up to 8 bits. And is defined using the OVSS [3: 0] bit in the ADC\_CFGR2 register.

The summing unit can produce a result of up to 20 bits (256 x 12-bit result), which is first shifted to the right. It is then truncated to 16 least significant bits before final transfer to the ADC\_DR data register, rounding the least significant bits left by the shift to the nearest value.

Note: If the shifted intermediate result exceeds 16 bits, the result is truncated as is without saturation.

Figure 14-13 20 bits ~ 16 bits result truncation

The figure below gives a numerical example of processing, from the raw 20-bit accumulated data to the final 16-bit result.

Figure. 14-14 Numerical example with 5-bit shift and rounding

The table below gives the data formats for various N and M combinations where the raw converted data is 0xFFFF.

Table 14-6 Maximum Output Results vs. N and M (gray cells indicate truncation)

| Over sampling ratio | Max Raw data | No-shift<br>OVSS = 0000 | 1-bit shift<br>OVSS = 0001 | 2-bit shift<br>OVSS = 0010 | 3-bit shift<br>OVSS = 0011 | 4-bit shift<br>OVSS = 0100 | 5-bit shift<br>OVSS = 0101 | 6-bit shift<br>OVSS = 0110 | 7-bit shift<br>OVSS = 0111 | 8-bit shift<br>OVSS = 1000 |
|---------------------|--------------|-------------------------|----------------------------|----------------------------|----------------------------|----------------------------|----------------------------|----------------------------|----------------------------|----------------------------|
| 2x                  | 0x1FFE       | 0x1FFE                  | 0x0FFF                     | 0x0800                     | 0x0400                     | 0x0200                     | 0x0100                     | 0x0080                     | 0x0040                     | 0x0020                     |

|      |         |        |        |        |        |        |        |        |        |        |
|------|---------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 4x   | 0x3FFC  | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 | 0x0400 | 0x0200 | 0x0100 | 0x0080 | 0x0040 |
| 8x   | 0x7FF8  | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 | 0x0400 | 0x0200 | 0x0100 | 0x0080 |
| 16x  | 0xFFF0  | 0xFFF0 | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 | 0x0400 | 0x0200 | 0x0100 |
| 32x  | 0x1FFE0 | 0xFFE0 | 0xFFF0 | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 | 0x0400 | 0x0200 |
| 64x  | 0x3FFC0 | 0xFFC0 | 0xFFE0 | 0xFFF0 | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 | 0x0400 |
| 128x | 0x7FF80 | 0xFF80 | 0xFFC0 | 0xFFE0 | 0xFFF0 | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF | 0x0800 |
| 256x | 0xFFF00 | 0xFF00 | 0xFF80 | 0xFFC0 | 0xFFE0 | 0xFFF0 | 0x7FF8 | 0x3FFC | 0x1FFE | 0x0FFF |

There is no change in the transition timing in oversampling mode: the sampling times remain equal throughout the oversampling sequence. Every N transitions provide a new data, delayed by  $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$  equivalent. The flags are set as follows:

- The end of sampling phase (EOSMP) is set after each sampling phase
- End of Transition (EOC) occurs every N transitions when oversampling results are available
- The end of sequence (EOS) occurs after the completion of the oversampled data sequence (i.e. after the  $N \times$  total sequence length conversion)

#### 14.3.16.1 ADC operating modes not supported during oversampling (single ADC mode and dual ADC mode)

In oversampling mode, injection break rules are not supported.

#### 14.3.16.2 Supported ADC operating modes when oversampling (single ADC mode)

In oversampling mode, most ADC operating modes remain the same:

- Single mode/continuous mode conversion
- Initiate ADC conversion via software or external trigger
- STOP ADC DURING TRANSFOR
- Read data via CPU/DMA
- Low Power Mode (AUTDLY)
- Programmable resolution: The result of the non-12-bits resolution conversion (according to the RES [1: 0] bit in the ADC\_CFGR register) is accumulated, truncated, rounded, and shifted in the same manner as the 12-bit conversion.

Note: Data alignment is not available when using oversampled data. The ALIGN bit in ADC\_CFGR is ignored and the data is always provided right-aligned. Offset correction is not supported in oversampling mode. When the ROVSE or JOVSE bit is set, the value of the OFFSETy\_EN bit in the ADC\_OFRy register is ignored (treated as a reset).

#### 14.3.16.3 Analog watchdog

The simulated watchdog functionality (AWD1SGL, AWD1EN, JAWD1EN) is maintained with the following differences:

- Ignore the RES [1: 0] bit and always use the full 12-bit values HT [11: 0] and LT [11: 0] for comparison
- Comparison is performed on the most significant 12 bits of the 16-bit oversampling result ADC\_DR [15: 4]

Note: Caution must be taken when using high shift values, which reduces the comparison range. For example, if the oversampling result is shifted by 4 bits, resulting in 12 bits of data right-aligned, a valid

analog watchdog comparison can only be performed on 8 bits. A comparison is made between ADC\_DR [11: 4] and HT [0: 7]/LT [0: 7], and HT [11: 8]/LT [11: 8] must be reset.

#### 14.3.16.4 Trigger Mode

The averager can also be used for basic filtering. While not a very powerful filter (slow roll-off and limited stopband attenuation), it can be used as a notch filter to suppress constant parasitic frequencies (usually from mains or switched mode power supplies). For this purpose, a specific discontinuity mode can be enabled using the TROVS bit in ADC\_CFGR2 in order to be able to have an oversampling frequency defined by the user and independent of the transition time itself.

The diagram below shows how the transition is initiated in response to a trigger in intermittent mode. If the TROVS bit is set, the contents of the DISCEN bit are ignored and treated as 1.

Figure 14-15 Oversampling mode triggering for rules (TROVS bit = 1)

#### 14.3.16.5 Oversample regular channels only

The regular oversampling pattern bit ROVSM defines how a regular oversampling sequence is re-stored if the sequence is interrupted by the injected transition:

- In continuous mode, the accumulation restarts from the last regular channel valid data (the trigger of the injection causes the previous transition to abort). This ensures that oversampling will be done regardless of the injection frequency (providing at least one rule transition between triggers to be done);
- In recovery mode, accumulation restarts from 0 (previous conversion results are ignored). This mode allows to guarantee that all data used for oversampling is converted back-to-back within a single time slot. Care must be taken to make the injection trigger period longer than the oversampling period length. If this condition is not obeyed, the oversampling will not be completed and the rule sequence will be blocked.

Figure 14-16 4x Example of oversampling rate

**14.3.16.6 Oversample only the injection channel**

The injection oversampling mode bit JOVSE enables oversampling only for transitions in the injection sequence.

**14.3.16.7 Automatic injection mode**

Automatically injected sequences can be oversampled and all conversion results stored in registers to save DMA resources. This mode is only available when both regular and injection oversampling are enabled: JAUTO = 1, ROVSE = 1, and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injection mode. The following diagram shows the sequence of transformations.

Figure 14-17 Automatic Injection Mode Oversampling

**14.3.16.8 Supports dual ADC mode when oversampling**

For synchronous injection mode and synchronous rule mode, oversampling can be enabled during dual ADC configuration. In this case, both ADCs must use exactly the same settings (including oversampling).

When regular or injection oversampling is enabled (ROVSE = 1 or JOVSE = 1), all other dual ADC modes are not supported.

**14.3.16.9 Summary of pattern combination**

The table below summarizes all combinations, including unsupported modes.

Table 14-7 Summary of Oversampler Modes

| Regular over-sampling ROVSE | Injection Over-sampling JOVSE | Oversampling mode ROVSM; 0 = continued<br>1 = resumed | Trigger Rule Mode TROVS | Description                        |
|-----------------------------|-------------------------------|-------------------------------------------------------|-------------------------|------------------------------------|
| 1                           | 0                             | 0                                                     | 0                       | Regular continuous mode            |
| 1                           | 0                             | 0                                                     | 1                       | -                                  |
| 1                           | 0                             | 1                                                     | 0                       | Rule recovery model                |
| 1                           | 0                             | 1                                                     | 1                       | Trigger Rule Recovery Mode         |
| 1                           | 1                             | 0                                                     | X                       | -                                  |
| 1                           | 1                             | 1                                                     | 0                       | Injection and rule recovery models |
| 1                           | 1                             | 1                                                     | 1                       | -                                  |
| 0                           | 1                             | X                                                     | X                       | Injection over-sampling            |

#### 14.3.17 Programmable sampling time

The ADC samples the input voltage over several ADC CLK cycles, and the number of sampling cycles is configured by SMP [2: 0] bits in the ADC\_SMPR1 and ADC\_SMPR2 registers. Each channel can be sampled using a different sampling time.

The total conversion time is calculated as follows:

$$t_{\text{conv}} = \text{sampling time} + 12.5 \text{ cycles}$$

Example:

fADC = 16 MHz And when sampling time = 3.5 cycles:

$$t_{\text{conv}} = 3.5 + 12.5 = 16 \text{ cycles} = 1 \mu\text{s}$$

#### 14.3.18 Conversion on external trigger

Converting a single channel or converting a sequence can be triggered by software or external events (e.g. timer capture, input pins). If EXTEN [1: 0] (for regular transitions) or JEXTEN [1: 0] (for injection transitions) is not equal to 00, an external event is able to trigger transitions with the selected polarity. The rule software trigger selection is valid once the software sets the bit ADSTART = 1, while the injected software trigger selection is valid once the software sets the bit JADSTART = 1. Any hardware or software triggers that occur during the conversion process will be ignored.

Note: While STRT/JSTRT is valid, a rule trigger/injection trigger occurs and will be ignored.

The following table provides the correspondence between the EXTEN [1: 0] and JEXTEN [1: 0] values and the trigger polarity.

Table 14-8 Rule External Trigger Configuration Trigger Polarity

| EXTEN [1: 0] | Source                                                                                |
|--------------|---------------------------------------------------------------------------------------|
| 00           | Hardware trigger detection disabled, software trigger detection enabled (rising edge) |
| 01           | Hardware triggering of rising edge detection                                          |
| 10           | Hardware triggering of falling edge detection                                         |
| 11           | Hardware triggered with detection on both rising and falling edges                    |

**Note:** The polarity of rules and injection triggers cannot be changed at any time

Table 14-9 Injection External Trigger Configuration Trigger Polarity

| JEXTEN [1: 0] | Source                                                                                |
|---------------|---------------------------------------------------------------------------------------|
| 00            | Hardware trigger detection disabled, software trigger detection enabled (rising edge) |
| 01            | Hardware triggering of rising edge detection                                          |

|    |                                                                    |
|----|--------------------------------------------------------------------|
| 10 | Hardware triggering of falling edge detection                      |
| 11 | Hardware triggered with detection on both rising and falling edges |

#### 14.3.19 Configurable resolution

Fast conversion can be performed by reducing the ADC resolution. The RES bit of the ADC\_CFGR register is used to select the number of bits available in the data register. The minimum conversion time for each resolution is as follows:

- 12 bits:  $3.5 + 12.5 = 16$  fADC cycles
- 10 bits:  $3.5 + 10.5 = 14$  fADC cycles
- 8-bit:  $3.5 + 8.5 = 12$  fADC cycles
- 6 bits:  $3.5 + 6.5 = 10$  fADC cycles

#### 14.3.20 DMA request

Because the value of the regular channel conversion is stored in a unique data register, DMA needs to be used when multiple regular channels are converted, which can avoid loss of data already stored in the ADC\_DR register.

Only the end of conversion of a regular channel generates a DMA request, which allows the transfer of its converted data from the ADC\_DR register to the destination location selected by the user. In the dual ADC mode, the data converted by the ADC2 is transmitted using the DMA function of the ADC1.

#### **14.3.21 Dual ADC Mode**

In devices with 2 ADCs, dual ADC mode can be used. In the DUAL ADC mode, the conversion is initiated by the ADC1 software/external touch trigger, depending on the mode selected by the DUAL [2: 0] bit.

Note: In dual ADC mode, when the transition is configured to be triggered by an external event, the user must set it to trigger only the master ADC and the slave ADC to be software triggered, which prevents accidental triggering of the slave transition. However, external triggers of the master and slave ADCs must be activated simultaneously.

There are 6 basic conversion modes:

- Synchronous injection mode
- Synchronization rule mode
- Fast crossover mode
- Slow crossover mode
- Alternate trigger mode
- Standalone mode

You can also use the above patterns in combination in the following ways:

- Sync Injection Mode + Sync Rule Mode

Figure 14-18 Dual ADC module diagram

1. An external trigger signal acts on ADC2, but it is not shown in this figure.
2. In dual ADC mode, the regular conversion data of ADC1 and ADC2 is included in the complete ADC1 data register (ADC1\_DR).

#### 14.3.21.1 Synchronous injection mode

In synchronous injection mode, ADC1 and ADC2 synchronously switch injection channel groups. The ADC\_JSQR registers of ADC 1 and ADC 2 specify all conversion channels of an injection group sequence, where the JL [1: 0] bit of the ADC\_JSQR register specifies the sequence length of the sequence.

When the ADEN bit is 1, once the ADC1 external trigger (selected by JEXTSEL [4: 0]) occurs, the ADC1 and ADC2 synchronization converts an injection sequence. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

Note:

1. Do not convert the same channel on two ADCs, that is, the sampling times of two ADCs on the same channel cannot overlap

- The channel sampling time of ADC1 and ADC2 synchronous conversion should be consistent

At the end of the conversion of ADC1 or ADC2:

- The converted data is stored in the ADC\_JDRx (x = 1-4) register of each ADC.
- When both ADC1/ADC2 injection channels are converted, the end of each channel conversion generates a JEOP event, and the end of the sequence generates a JEOS event.

Figure 14-19 4 Synchronous injection mode on channels

#### 14.3.21.2 Synchronization rule pattern

When synchronizing rule mode, ADC1 and ADC2 synchronously convert rule channel groups. The ADC\_SQRx (x = 1-4) register of ADC 1 and ADC 2 specifies a regular sequence of all conversion channels, where the L [1: 0] bit specifies the sequence length. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

When the ADEN bit is 1, once the ADC1 external trigger (selected by EXTSEL [4: 0]) occurs, the ADC1 and ADC2 synchronization will convert a regular sequence. (Note: Users should not convert the same channel on two ADCs, that is, the sampling times of two ADCs on the same channel cannot overlap)

At the end of the conversion of ADC1 or ADC2:

- A 32-bit DMA transfer request is generated (if the DMA bit is set). The upper 16 bits of the 32-bit ADC1\_DR register transferred to the SRAM contain the converted data of ADC2 and the lower 16 bits contain the converted data of ADC1.
- When all ADC1/ADC2 regular channels are converted, an EOC event is generated at the end of each channel conversion, and an EOS event is generated at the end of the sequence.

Notes:

- In synchronization rule mode, sequences with the same length must be converted or the trigger interval must be longer than the longer sequence of the two sequences. Otherwise, when the conversion of the longer sequence is not completed, the ADC conversion with the shorter sequence will be restarted.
- The channel sampling time of ADC1 and ADC2 synchronous conversion should be consistent.

Figure 14-20 Synchronization rule pattern on 16 channels

### 14.3.21.3 Fast crossover mode

Fast crossover mode, ADC1 and ADC2 alternately switch one channel. This mode only applies to regular channel groups (usually one channel), and SQ1 of ADC 1 and ADC 2 defines the channel to be converted. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

When the ADEN bit is 1, once the ADC1 external trigger (selected by EXTSEL [4: 0]) occurs, ADC1 and ADC2 alternately transition a regular channel.

The external trigger source comes from the regular channel multiplexer of ADC1. After the external trigger is generated:

- ADC2 starts immediately
- ADC1 starts after 7 ADC clock cycles delay

If the CONT bits of ADC1 and ADC2 are set at the same time, the two selected ADC rule channels will be converted consecutively. The end of ADC1 conversion generates an EOC flag, which generates a 32-bit DMA transfer request (if the DMA bit is set). The 32-bit data of the ADC1\_DR register is transferred to the SRAM. The upper 16 bits of ADC1\_DR contain the converted data of ADC2, and the lower 16 bits contain the converted data of ADC1. The end of each channel transition produces an EOC event, and the end of the sequence produces an EOS event.

Note: The maximum allowable sampling time is  $< 7 \text{ ADCCLK}$  cycles, so as to avoid the overlap of two sampling cycles when ADC1 and ADC2 convert the same channel. (Continuous Mode Maximum Sampling Time  $< 4 \text{ ADCCLK}$  Cycles)

Figure 14-21 Fast crossover mode in continuous transition mode on one channel

### 14.3.21.4 Slow crossover mode

This mode is only available for regular channel groups (only one channel). The external trigger source comes from the regular channel multiplexer of ADC1. After the external trigger is generated:

- ADC2 starts immediately
- ADC1 starts after 14 ADC clock cycles delay
- After delaying the second 14 ADC cycles, ADC2 starts again, and so on.

Note: The maximum allowable sampling time is  $< 14 \text{ ADCCLK}$  cycles to avoid overlap with the next transition.

After the ADC1 conversion is completed, an EOC flag is generated, and a 32-bit DMA transfer request is generated (if the DMA bit is set). The 32-bit data of the ADC1\_DR register is transferred to the SRAM. The upper 16 bits of ADC1\_DR contain the converted data of ADC2, and the lower 16 bits contain the

converted data of ADC1. The end of each channel transition produces an EOC event, and the end of the sequence produces an EOS event. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

The CONT bit cannot be set in this mode because it will continuously switch the selected regular channel.

Note: The application must ensure that when using crossover mode, no external trigger can be generated for the injection channel.

Figure 14-22 Slow crossover pattern of on one channel

#### 14.3.21.5 Alternate trigger mode

This mode only applies to injection channel groups. The external trigger source comes from the injection channel multiplexer of ADC1. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

If the injection scan mode is used on ADC1 and ADC2:

- When the first trigger is generated, all injection group channels on ADC1 are switched.
- When the second trigger arrives, all injection group channels on ADC2 are switched.
- So cycling...

If a JEOS interrupt is allowed, a JEOS interrupt is generated after all ADC1 injection group channel transitions. The end of each channel transition produces a JEOC event, and the end of the sequence produces a JEOS event.

If allowed to generate a JEOS interrupt, generate a JEOS interrupt after all ADC2 injection group channel transitions. The end of each channel transition produces a JEOC event, and the end of the sequence produces a JEOS event.

When all injection group channels have been switched, if another external trigger is generated, the ADC1 injection group channel starts switching again.

Figure 14-23 Alternate triggering-group of injection channels per ADC

If the injection interrupt mode is used on both ADC1 and ADC2:

- When the first trigger is generated, the first injection channel on ADC1 is switched.
- When the second trigger arrives, the first injection channel on ADC2 is switched.
- So cycling...

If a JEOS interrupt is allowed, a JEOS interrupt is generated after all ADC1 injection group channel transitions. The end of each channel transition produces a JEOC event, and the end of the sequence produces a JEOS event.

If allowed to generate a JEOS interrupt, generate a JEOS interrupt after all ADC2 injection group channel transitions. The end of each channel transition produces a JEOC event, and the end of the sequence produces a JEOS event.

When all injection group channels have been converted, if another external trigger is generated, the alternate trigger process is restarted.

Figure 14-24 Alternate triggering-4 injection channels on each ADC in discontinuous mode

#### 14.3.21.6 Standalone mode

In this mode, each ADC works independently and is not related to each other.

#### 14.3.21.7 Hybrid rule/injection synchronization pattern

The rule group synchronization transition may be interrupted to initiate the synchronization transition of the injection group. When the sampling is finished, EOSMP is generated, and if EOSMPIE is set, an interrupt is generated.

Notes:

1. In the hybrid regular/injection synchronization mode, sequences with the same time length must be converted or the trigger interval must be longer than the longer sequence of the two sequences, otherwise ADC conversion with shorter sequence may be restarted when the conversion of the longer sequence has not been completed.
2. The channel sampling times of ADC1 and ADC2 synchronous conversion remain consistent

Figure 14-25 Mixed Rule/Injection Synchronization Mode-scan Mode

### 14.3.22 Temperature sensor and internal reference voltage

Temperature sensors may be used to measure device node temperature ( $T_J$ ). The temperature sensor is internally connected to the ADC1\_CH16 channel, which converts the voltage output by the sensor into a digital value. When not in use, the sensor can be put in power down mode.

The output voltage of the temperature sensor changes linearly with the temperature. Due to the change of the production process, the offset of the temperature change curve will be different on different chips. The internal temperature sensor is more suited to applications that detect temperature variations instead of absolute temperatures. If accurate temperature readings are needed, an external temperature sensor part should be used.

Note: The VSENSESEL, VREFEN bits must be set to activate the transition of the internal channels: ADC1\_CH16 (temperature sensor) and ADC1\_CH18 (VREFINT).

Figure 14-26 Temperature Sensor Channel Block Diagram

Main features

Reading the temperature

To use the sensor:

1. Select ADC1\_CH16
2. Select a sampling time that is greater than the minimum sampling time specified in the datasheet.
3. VSENSESEL position 1 in the ADC1\_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion by setting the ADEN bit (or by external trigger).
5. Read the resulting VSENSE data in the ADC data register
6. Calculate the temperature using the following formula:

$$\text{Temperature (}^{\circ}\text{C)} = \{(\text{VSENSE}-\text{V30})/\text{Avg\_Slope}\} + 30^{\circ}\text{C}$$

with:

V30 = VSENSE value at 30 °C

Avg\_Slope = Average Slope for curve between Temperature vs. VSENSE (given in mV/° C or μV/ °C).  
(For information on actual values of V30 and Avg\_Slope, see the Electrical Characteristics section in the datasheet.)

Note: It takes a settling time for the sensor to wake up from power-down mode, and the correct VSENSE is output after the startup time. The ADC also requires a setup time after power-up, so in order to shorten the delay, ADEN and VSENSESEL should be positioned at position 1 at the same time.

#### 14.3.23 Battery monitoring

Because the VBAT voltage can vary, the VBAT pin needs to be internally connected to the bridge distributor to ensure the correct operation of the ADC.

The bridge automatically enables VBAT/3 to connect to the ADC1/3\_CH17 input channel.

#### 14.3.24 ADC interrupts

For each ADC, the following interrupts are generated:

- At the end of any transition of the rule group (flag EOC)
- At the end of a sequence of rule groups (flag EOS)
- At the end of any transition of the injection group (flag JEOC)
- At the end of an injection group sequence (flag JEOS)
- When simulated watchdog detection occurs (flags AWD1, AWD2, and AWD3)
- When the sampling phase is over (flag EOSMP)

Independent interrupt enable bits have flexibility.

Table 14-11 Interrupts per ADC

| Interrupt event                          | Event flag | Enable control bit |
|------------------------------------------|------------|--------------------|
| A rule conversion ends                   | EOC        | EOCIE              |
| A rule sequence ends                     | EOS        | EOSIE              |
| An injection transition ends             | JEOC       | JEOCIE             |
| An injection sequence ends               | JEOS       | JEOSIE             |
| Simulated Watchdog 1 State Position bit  | AWD1       | AWD1IE             |
| Simulated Watchdog 2 status position bit | AWD2       | AWD2IE             |
| Simulated Watchdog 3 State Position bit  | AWD3       | AWD3IE             |
| End of sampling phase                    | EOSMP      | EOSMPIE            |

## 14.4 Register Description (for each ADC)

ADC1 register base address: 0x4001\_2400

ADC2 register base address: 0x4001\_2800

ADC3 register base address: 0x4001\_3C00

### 14.4.1 ADC interrupt and status register (0x00: ADC\_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

## 15. Digital-to-analog converter (DAC)

### 15.1 Introduction

The 12-bit buffered DAC channel can be used to convert digital signals into analog voltage signal outputs. The DAC can be configured in 8-bit or 12-bit mode, or can be used in conjunction with a DMA controller. When the DAC is operating in 12-bit mode, the data can be left justified or right justified. The DAC module has two output channels, each with a separate converter. In dual-DAC mode, the two channels can be converted independently, or they can be converted simultaneously and update the output of the two channels synchronously. The DAC can input the reference voltage VREF+ through the pin for more accurate conversion results.

#### 15.1.1 Main Features

- 2 DAC converters: 1 output channel per converter
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave generation
- Triangular-wave generation
- Dual DAC channel independent or simultaneous conversions
- DMA capability for each channel
- Support DMA underflow error detection
- Conversion on external trigger
- Input voltage reference, VREF+

### 15.1.2 CAN block diagram

Figure 15-1 DAC module block diagram

| Pin name  | Signal type                              | Description                                                            |
|-----------|------------------------------------------|------------------------------------------------------------------------|
| VCCA      | Input, analog supply                     | Analog power supply                                                    |
| VSSA      | Input, analog supply ground              | Ground for analog power supply                                         |
| VREF+     | Input, analog positive reference voltage | DAC positive reference voltage,<br>$2.3\text{ V} \leq VREF+ \leq VCCA$ |
| DACx_OUT1 | Analog output signal                     | DACx analog output                                                     |

Note: Before enabling the DAC module, the GPIO port (PA4 corresponds to DAC1, PA5 corresponds to DAC2) should be configured with bit simulation mode.

## 15.2 DAC functional description

### 15.2.1 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC\_CR register. After a startup time (tWAKEUP), the DAC channel x is enabled.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

### 15.2.2 Enable DAC Output Cache

The DAC integrates two output buffers that can be used to reduce the output impedance, and to drive external loads directly without having to add an external operational amplifier. Each DAC channel output buffer can be enabled and disabled using the corresponding BOFFx bit in the DAC\_CR register.

### 15.2.3 DAC data format

Depending on the selected configuration mode, the data has to be written in the specified register as described below:

Single DAC channelx, there are three possibilities:

- 8-bit data right-aligned: the user must write the data to register DAC\_DHR8Rx [7: 0] bits (actually stored in register DAC\_DHRx [11: 4] bits)
- 12-bit data left alignment: user must write data to register DAC\_DHR12Lx [15: 4] bits (actually stored in register DAC\_DHRx [11: 0] bits)
- 12-bit data right-aligned: user must write data to register DAC\_DHR12Rx [11: 0] bits (actually stored in register DAC\_DHRx [11: 0] bits)

Depending on the operation of the DAC\_DHRyyx register (yyy refers to different data formats and alignments), the written data is transferred to the DAC\_DHRx register (DHRx is the internal data storage register x) after the corresponding shift. Subsequently, the contents of the DAC\_DHRx register are automatically transferred to the DAC\_DORx register by a software trigger or an external trigger.

Figure 15-2 1 Data Register of DAC Channel Mode

Dual DAC channels, there are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded into DAC\_DHR8RD [7:0] bits (stored into DAC\_DHR1[11:4] bits) and data for DAC channel2 to be loaded into DAC\_DHR8RD [15:8] bits (stored into DAC\_DHR2[11:4] bits)
- 12-bit left alignment: data for DAC channel1 to be loaded into DAC\_DHR12LD[15:4] bits (stored into DAC\_DHR1[11:0] bits) and data for DAC channel2 to be loaded into DAC\_DHR12LD [31:20] bits (stored into DAC\_DHR2[11:0] bits)

- 12-bit data right alignment: the user must write DAC channel 1 data into register DAC\_DHR12RD [11: 0] bits (actually stored in registerDAC\_ DHR1 [11: 0] bits) and DAC channel 2 data into register DAC\_DHR12RD [27: 16] bits (actually stored in register DAC\_ DHR2 [11: 0] bits)

Depending onthe operation of the DAC\_DHRyyyD (yyyrefers to different data formats and alignments) registers, the written data is transferred to theDAC\_ DHR1 andDAC\_ DHR2 registersafter correspond- ing shifts (DAC\_ DHR1 andDAC\_ DHR2 are internal data holding registers). The DAC\_DHR1 and DAC\_DHR2 registers will then be loaded into the DAC\_DOR1 and DAC\_DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 15-3 Data registers in dual-DAC channel mode

#### 15.2.4 DAC conversion

Data cannot be written directly to the register DAC\_DORx, any data output to the DAC channel x must be written tothe DAC\_DHRxregister (data is actually written to the DAC\_DHR8Rx, DAC\_DHR12Lx, DAC\_DHR12Rx, DAC\_DHR8RD, DAC\_DHR12LD, or DAC\_DHR12RD registers).

If hardware trigger is not selected (TENx position '0' of register DAC\_CR),the data stored in register DAC\_ DHRx is automatically transferred toregister DAC\_DORxafter 1 APB1 clock cycle. If the hard- ware trigger is selected (TENx position '1' of the register DAC\_CR), the data transfer is completed 3 APB1 clock cycles after the trigger occurs.

Once data is loaded fromthe DAC\_DHRxregister into the DAC\_DORx register,the output becomes active after the elapse of a setup time( $t_{SETTLING}$ ), the length of whichvaries depending on the supply voltageand analog output load.

Figure 15-4 Timing diagram for conversion when TEN = 0

### 15.2.5 DAC output voltage

The digital input is linearly converted to an analog voltage output via DAC, which ranges from 0 to  $V_{REF}$  +.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DAC output} = V_{REF} + x \text{ (DOR/4096)}.$$

### 15.2.6 DAC trigger selection

If the TENx bit is set to 1, the DAC transition may be triggered by some external event (timing counter, external interrupt line, and software operation). The TSELx[3:0] control bits determine which one, out of 12 possible events, will trigger conversion.

Table 15-1 External triggers

| TSELx [3: 0] | DAC trigger signal selection |            |
|--------------|------------------------------|------------|
|              | DAC1                         | DAC2       |
| 0            | sw                           | sw         |
| 1            | tim8_trgo                    | tim8_trgo  |
| 2            | tim7_trgo                    | tim7_trgo  |
| 3            | tim15_trgo                   | tim15_trgo |
| 4            | tim2_trgo                    | tim2_trgo  |
| 5            | tim4_trgo                    | tim4_trgo  |
| 6            | exti9                        | exti9      |
| 7            | tim6_trgo                    | tim6_trgo  |
| 8            | tim3_trgo                    | tim3_trgo  |
| 9            | tim18_trgo                   | tim18_trgo |
| 10           | tim1_trgo                    | tim1_trgo  |
| 11           | tim5_trgo                    | tim5_trgo  |

Each time the DAC detects a rising edge output from the selected timer TRGO or external interrupt line 9 (event), the data most recently stored in the register DAC\_DHRx is transferred to the register DAC\_DORx. After 3 APB1 clock cycles, the register DAC\_DORx is updated to a new value.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. After data is transferred from the DAC\_DHRx register to the DAC\_DORx register, the SWTRIG bit is automatically cleared '0' by the hardware.

Note:

1. The TSELx [3: 0] bit can no longer be changed when ENx is '1'.
2. If software trigger is selected, only one APB1 clock cycle is required to transfer data from register DAC\_DHRx to register DAC\_DORx.
3. When the output cache is enabled (DAC\_CR.BOFFx = 0), the trigger frequency cannot exceed 1 M; When the output buffer is turned off (DAC\_CR.BOFFx = 1), the frequency of triggering cannot exceed 15 M.

## 15.2.7 DMA functionality

### 15.2.7.1 DMA request

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

If DAC\_CR.DMAENx position '1', once an external trigger (not a software trigger) occurs, a DMA request will be generated after 3 clock cycles, and then the data of the DAC\_DHRx register is transferred to the DAC\_DORx register.

In dual DAC mode (i.e. using the DAC\_DHR12RD or DAC\_DHR12LD or DAC\_DHR8RD register), only one bit in DAC\_CR.DMAENx should be set.

### 15.2.7.2 DMA underrun

The DMA requests of the DAC do not have a buffer queue, so if the second external trigger arrives before receiving a reply to the first external trigger (the first request), no new DMA request will be issued and the DMA underflow flag DMAUDRx in the DAC\_SR register will be set to "1", reporting an error. The DMA data transfer is then disabled and no more DMA requests are processed. The DAC channel continues to convert the original data.

The software shall clear the flag by writing "1" to the register DMAUDRx, zero the DMAEN position of the used DMA channel, and re-initialize the DMA and DAC channels in order to properly restart the DMA transfer. At the same time, the software should modify the DAC trigger conversion frequency to reduce the DMA workload to avoid the recurrence of DMA underflow.

For each DAC channel, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC\_CR register is enabled.

## 15.2.8 Noise generation

A linear feedback shift register (LFSR) may be utilized to generate pseudo noise of varying amplitude. Set the DAC\_CR.WAVE [1: 0] bit to '01' to select the DAC noise generation function. The preloaded value in LFSR is 0xAAA. According to a specific algorithm, the value of this register is updated after 3 APB1 clock cycles after each trigger event.

Setting the DAC\_CR.MAMPx [3: 0] bit can mask some or all of the LFSR data, so that the resulting value of LFSR is added to the value of DAC\_DHRx. If the resulting value overflows, the maximum value that the register can keep is written to DAC\_DORx, and if the resulting value does not overflow, the value is written to DAC\_DORx.

If the register LFSR value is 0x000, a '1' (anti-lock mechanism) is injected.

Setting the DAC\_CR.WAVEx [1: 0] position '0' may reset the generation algorithm of the LFSR waveform.

Figure 15-5 DAC LFSR register algorithm

Figure 15-6 DAC conversion with LFSR waveform generation (software triggered)

Figure 15-7 DAC conversion with LFSR waveform generation (hardware triggered)

Note:

1. In order to generate noise, the DAC trigger must be enabled, i.e. set the TENx bit of the DAC\_CR register to '1';
2. If the value of DAC\_DHR changes, the value of the LFSR register will be reset to 0xAAA;
3. If DAC\_CR.TENx changes from "1" to "0", the value of the LFSR register will also be reset to 0xAAA.

### 15.2.9 Triangle-wave generation

A small amplitude triangular wave can be added to DC or slowly changing signals. Set the DAC\_CR.WAVEx [1: 0] bit to "10" or "11" to select the triangular wave generation function of the DAC. Set the DAC\_CR.MAMPx[3: 0] bit to select the amplitude of the triangular wave. The internal triangular wave counter accumulates 1 for 3 APB1 clock cycles after each trigger event. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and soon.

It is possible to reset triangle wave generation by resetting the DAC\_CR.WAVEx[1:0] bits.

Note: When the base value is the maximum value of the register DAC\_DORx, the output of DAC\_DORx is the maximum value regardless of the value of MAMPx.

Figure 15-8 DAC Triangular Wave Generation

Figure 15-9 DAC conversion with triangulation generation of graphs (software triggered)

DAC conversion15-10 with triangulation generation (hardware triggered)

Note:

1. In order to generate a triangular wave, DAC trigger must be enabled, i.e. set the TENx bit of the DAC\_CR register to '1';
2. The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
3. Change the value of DAC\_DHR, and the triangular wave counter is reset to 0;
4. If DAC\_CR.TENx changes from "1" to "0", the triangular wave counter is also reset to 0.

### 15.2.10 Dual DAC channel conversion

When two DACs are required to work at the same time, in order to make more effective use of bus bandwidth, the DAC integrates three registers for dual DAC mode: DHR8RD, DHR12RD and DHR12LD. Only one register needs to be accessed to drive two DACs at the same time. Operation of DAC channels. Eleven possible conversion modes are possible using the dual DAC channels and these dual registers. These conversion modes can still be operated through a separate DAC\_DHRx register when only one DAC channel is used.

All modes are described in the paragraphs below.

#### 15.2.10.1 Independent trigger without use of waveform generator

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure different trigger sources by setting different values in the DAC\_CR.TSEL1 [3:0] and DAC\_CR.TSEL2 [3:0] bits;
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a DAC channel 1 trigger event occurs, the value of register DHR1 (after 3 APB1 clock cycles delay) is passed into register DAC\_DOR1.

When a DAC channel 2 trigger event occurs, the value of register DHR2 (after 3 APB1 clock cycles delay) is passed into register DAC\_DOR2.

#### 15.2.10.2 Independent triggers using the same LFSR

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure different trigger sources by setting different values in the DAC\_CR.TSEL1 [3:0] and DAC\_CR.TSEL2 [3:0] bits;
- Configure the two DAC channel WAVEx[1:0] bits as "01" and the same LFSR mask value in the MAMPx[3:0] bits;
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a DAC channel 1 trigger event occurs, the LFSR1 counter value with the same mask is added to the DAC\_DHR1 register value, delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_DOR1, and then the LFSR1 counter is updated.

When a DAC channel 2 trigger event occurs, the LFSR2 counter value with the same mask is added to the DAC\_DHR2 register value, delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_DOR2, and then the LFSR2 counter is updated.

#### 15.2.10.3 Independent triggering using different LFSRs

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure different trigger sources by setting different values in the DAC\_CR.TSEL1 [3:0] and DAC\_CR.TSEL2 [3:0] bits;
- Configure the two DAC channel DAC\_CR.WAVEx[1:0] bits as "01" and the different LFSR mask

value in the MAMPx[3:0] bits;

- Load the dual DAC channel conversion data into the required DHR registers (DHR12RD, DHR12LD, or DHR8RD).

When a DAC channel 1 trigger event occurs, the LFSR1 counter value masked according to DAC\_CR.MAMP1 [3: 0] is added to the DAC\_ DHR1 register value, delayed by 3 APB1 clock cycles, and the result is passed into the register DAC\_ DOR1, and then the LFSR1 counter is updated.

When a DAC channel 2 trigger event occurs, the LFSR2 counter value masked according to DAC\_CR.MAMP2 [3: 0] is added to the DAC\_ DHR2 register value, delayed by 3 APB1 clock cycles, and the result is passed into the register DAC\_ DOR2, and then the LFSR2 counter is updated.

#### 15.2.10.4 Independent trigger with same triangle generation

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure different trigger sources by setting different values in the DAC\_CR.TSEL1 [3:0] and DAC\_CR.TSEL2 [3:0] bits;
- Configure the two DAC channel WAVEx [1:0] bits as “1x” and the same maximum amplitude value in the MAMPx [3:0] bits
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a DAC channel 1 trigger event occurs, the same triangular wave amplitude plus the DAC\_ DHR1 register value is delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_ DOR1, and then the DAC channel 1 triangular wave counter is updated.

When a DAC channel 2 trigger event occurs, the same triangular wave amplitude plus the DAC\_ DHR2 register value is delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_ DOR2, and then the DAC channel 2 triangular wave counter is updated.

#### 15.2.10.5 Independent trigger with different triangle generation

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure different trigger sources by setting different values in the DAC\_CR.TSEL1 [3:0] and DAC\_CR.TSEL2 [3:0] bits;
- Configure the two DAC channel WAVEx [1:0] bits as “1x” and the different maximum amplitude value in the DAC\_CR.MAMPx [3:0] bits
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a DAC channel 1 trigger event occurs, the triangular wave amplitude set by DAC\_CR.MAMP1 [3: 0] plus the DAC\_ DHR1 register value, delay 3 APB1 clock cycles, and the result is passed into the register DAC\_ DOR1, and then the DAC channel 1 triangular wave counter is updated.

When a DAC channel 2 trigger event occurs, the triangular wave amplitude set by DAC\_CR.MAMP2 [3: 0] plus the DAC\_ DHR2 register value, delay 3 APB1 clock cycles, and the result is passed into the register DAC\_ DOR2, and then the DAC channel 2 triangular wave counter is updated.

**15.2.10.6 Simultaneous non-hardware conversion**

Follow the following procedure to set the DAC conversion mode:

- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

In this configuration, after one APB1 clock cycle, the values of the DAC\_DHR1 and DAC\_DHR2 registers are passed into the DAC\_DOR1 and DAC\_DOR2 registers, respectively.

**15.2.10.7 Simultaneous trigger without wave generation**

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure the same trigger source for both DAC channels by setting the same value in the DAC\_CR.TSEL1[3:0] and DAC\_CR.TSEL2[3:0] bits;
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a trigger event occurs, after a delay of 3 APB1 clock cycles, the values of the DAC\_DHR1 and DAC\_DHR2 registers are passed into the DAC\_DOR1 and DAC\_DOR2 registers, respectively.

**15.2.10.8 Simultaneous trigger with same LFSR generation**

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- By setting the DAC\_CR.TSEL1 [3: 0] and DAC\_CR.TSEL2 [3: 0] bits to the same value, two DAC channels are configured to use the same trigger source respectively;
- Configure the two DAC channel DAC\_CR.WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits;
- Loading dual DAC channel conversion data into the required DHR registers (DHR12RD, DHR12LD, or DHR8RD);

When a trigger event occurs, the masked LFSR1 counter value set by DAC\_CR.MAMP1 [3: 0] is added to the DAC\_DHR1 register value, delayed by 3 APB1 clock cycles, and the result is passed into the DAC\_DOR1 register, and then the LFSR1 counter is updated.

Similarly, the masked LFSR2 counter value set by DAC\_CR.MAMP2 [3: 0] is added to the DAC\_DHR2 register value, delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_DOR2, and then the LFSR2 counter is updated.

**15.2.10.9 Simultaneous trigger with different LFSR generation**

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure the same trigger source for both DAC channels by setting the same value in the DAC\_CR.TSEL1[3:0] and DAC\_CR.TSEL2[3:0] bits;
- Configure the two DAC channel DAC\_CR.WAVEx[1:0] bits as “01” and the different LFSR mask value in the MAMPx[3:0] bits;
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a trigger event occurs, the LFSR1 counter value with the same mask is added to the DAC\_DHR1 register value, delayed by 3 APB1 clock cycles, and the result is passed into register DAC\_DOR1, and then the LFSR1 counter is updated.

At the same time, the LFSR2 counter value with the same mask is added to the DAC\_DHR2 register value, delayed by 3 APB1 clock cycles, and the result is passed into the register DAC\_DOR2, and then the LFSR2 counter is updated.

#### 15.2.10.10 Simultaneous trigger with same triangle generation

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure the same trigger source for both DAC channels by setting the same value in the DAC\_CR.TSEL1[3:0] and DAC\_CR.TSEL2[3:0] bits
- Configure the two DAC channel WAVEx [1:0] bits as "1x" and the same maximum amplitude value in the MAMPx [3:0] bits
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a trigger event occurs, the same triangular wave amplitude is added to the DAC\_DHR1 register value. After a delay of 3 APB1 clock cycles, the result is passed into the register DAC\_DOR1, and then the triangular wave counter is updated.

At the same time, the same triangular wave amplitude is added to the DAC\_DHR2 register value, and after a delay of 3 APB1 clock cycles, the result is passed into the register DAC\_DOR2, and then the triangular wave counter is updated.

#### 15.2.10.11 Simultaneous trigger with different triangle generation

Set the DAC conversion mode in the following order:

- Set the two DAC channel trigger enable bits DAC\_CR.TEN1 and DAC\_CR.TEN2;
- Configure the same trigger source for both DAC channels by setting the same value in the DAC\_CR.TSEL1[3:0] and DAC\_CR.TSEL2[3:0] bits
- Configure the two DAC channel WAVEx [1:0] bits as "1x" and the different maximum amplitude value in the DAC\_CR.MAMPx [3:0] bits
- Load the dual DAC channel conversion data into the required DHR register (DHR12RD, DHR12LD, or DHR8RD).

When a trigger event occurs, the triangular wave amplitude set by DAC\_CR.MAMP1 [3: 0] is added to the DAC\_DHR1 register value, and after a delay of 3 APB1 clock cycles, the result is passed into the register DAC\_DOR1, and then the triangular wave counter is updated.

At the same time, the triangular wave amplitude set by DAC\_CR.MAMP2 [3: 0] is added to the DAC\_DHR2 register value, delayed by 3 APB1 clock cycles, and the result is passed into the register DAC\_DOR2, and then the triangular wave counter is updated.

#### 15.2.11 DAC output clock

The DAC output clock (DAC\_CLK) is the analog sample data clock, which is only valid when DAC\_CR.ENx is "1". When selecting hardware trigger, it is detected that 5 APB1 cycles after the rising edge of the hardware trigger TRGO are set to "1", and 0 is cleared after holding 3 APB1 cycles; When

selecting software trigger, it is detected that 3 APB1 cycles after the rising edge of software trigger are set to "1", and 0 is cleared after maintaining 3 APB1 cycles; When not triggering is selected, 2 APB1 periods in which data changes are detected are set to "1", and 0 is cleared after holding 3 APB1 periods. Note: After 1 APB1 cycle when TENx changes from "1" to "0", the data of DAC\_DOR is updated to the data in the DAC\_DHR register. When DAC\_DOR is updated to a new value, a DAC\_CLK is generated; Otherwise, no DAC\_CLK will be generated.

## 15.3 TIMx registers

These peripheral registers must be operated in a word (32-bit) manner.

## 16. Voltage Reference Buffer

### 16.1 Introduction

The embedded VREFBUF is used as the ADC reference voltage, and this voltage can also be output through VREF+.

### 16.2 Functional description

The embedded reference voltage supports four voltages and can be configured through the VREFBUFSEL of ADC\_CCR:

- VREFBUFSEL = 00: 1.08 V
- VREFBUFSEL = 01: 2.048 V
- VREFBUFSEL = 10: 2.5 V
- VREFBUFSEL = 11: 2.9 V

By setting VREFBUFEN of ADC\_CCR to enable VREFBUF, the user must set VREFBUFSEL and the VREFBUF output reaches the desired value.

## 17. Comparator (COMP)

### 17.1 Introduction

The chip integrates four general-purpose comparators (COMP), namely COMP1,COMP2,COMP3 and COMP4. The COMP1/4 module can be used as a separate module or in combination with timer.

The I/O used as the comparator analog function must be configured in analog mode in the GPIO register and need to enable the PAD of the comparator mapping in the SYSCFG.P \* \_ANA2EN (\* = A, B, C, F) register.

The COMP features:

- Low power mode wake-up
- Analog signal conditioning
- Current control of Cycle by cycle when connected to the PWM output from the timer

#### 17.1.1 Main features

- Supports voltage comparison function, each comparator has configurable positive or negative input for flexible voltage selection
  - Multiple I/O pins
  - 64 gear voltage division of VCC/VREFCMP
  - Temperature sensor output
  - DAC output
- Programmable speed and power consumption
- Programmable hysteresis function
- Write protection for configuration registers (LOCK function)
- The output can be connected to the input of I/O or timer
  - OCREF\_CLR event (cycle by cycle current control)
  - Brakes for fast PWM shutdown
- Each COMP has interrupt generation capability and is used as a chip to wake up from low power mode (sleep/low power sleep/stop mode) (via EXTI)
- Provides software to configure the digital filtering time to enhance the anti-interference capability of the device
- It supports output blanking to reduce switching noise.
- Support window comparison function

### 17.1.2 CAN block diagram

Figure 17-1 COMP structural block diagram

## 17.2 COMP functional description

### 17.2.1 Inputs and outputs of COMP

The comparator output can be connected to the I/O pin through an alternate function at the GPIO.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down braking of PWM signal when brake input is connected
- OCREF\_CLR event (cycle by cycle current control)
- Input capture for timing measures

See the following table for the connection relationship between comparator output and other modules.

### 17.2.2 Clock and Reset of COMP

The COMP module has two clock sources:

1. PCLK (APB clock) for configuring registers
2. COMP clock, used to simulate the clock of the circuit after the output of the comparator (analog output latch circuit, glitch filter circuit, etc.), can be selected as PCLK, LSE or LSI. When it is necessary to work in stop mode, LSE or LSI is selected(selected byRCC\_CCIPR.COMPxSEL).

Note:

1. PCLK and COMP CLK are simultaneously enabled by the RCC\_APB2ENR.COMPEN bit. If enabled, PCLK and COMP CLK are turned off, and if enabled, PCLK and COMP CLK are turned on simultaneously.
2. Before entering Stop mode, it is recommended to configure COMP CLK to LSI or LSE; Then go into stop mode.

The reset signal of the COMP module includes APB reset source and COMP module software reset source

1. APB reset, used to reset the COMP register
2. COMP software reset, used to reset the circuit after the analog comparator output (analog output latch circuit, glitch filter circuit, etc.)

Note: When the reset signal in RCC\_APB2RSTR is enabled, the entire COMP module is reset, including the registers and the circuit used to simulate the output of the comparator.

### 17.2.3 Filtering function of COMP

If the working environment of the chip is harsh, the output of the comparator will appear noisy signals. When the digital filter module is enabled, all noise signals whose pulse width is less than the set time of COMPx\_FR.FLT CNT [15: 0] in the output waveform of the comparator can be filtered out. If the digital filter module is disabled, the output signal of the digital filter module is the same as the input signal.

Note: To set the COMP filtering time, enabling filtering should be completed before COMPx\_CSR.EN is enabled.

The filtering schematic is as follows:

Figure 17-2 COMP filtering schematic diagram

### 17.2.4 COMP's Locking Mechanism

The comparator can be used in safety aspects, such as overcurrent and temperature protection. For applications with specific functional safety requirements, it is necessary to ensure that the comparator registers cannot be overwritten in case of false register access and PC (program counter) confusion.

Thus, the comparator control and status registers can be write-protected (read-only).

If the writing of the register is complete, the COMPx\_CSR.LOCK bit is set to 1, which makes the entire register read-only, including the COMPx\_CSR.LOCK bit.

The write protection can only be reset by the system reset of the chip.

### 17.2.5 Output blanking of COMP

The purpose of the blanking function is to prevent current from tripping at the beginning of the regulated PWM cycle due to a short current spike (usually the recovery current in the anti-parallel diode of the power switch). The blanking function is realized by setting the output comparison signal of the timer. The blanking source for each comparator channel is individually selected by the software via the BLANKSEL [2: 0] bit of the corresponding COMPx\_ CSR register. The inverted blanking signal is logically AND with the comparator output to produce the output of the comparator channel.

Figure 17-3 comparator blanking

### 17.2.6 Window Mode of COMP

The comparator in window mode is simply referred to as a window comparator, and the function of the window comparator is to monitor whether the analog voltage is within the low and high threshold ranges. Window comparators can be created using COMP1 and COMP2, and COMP3 and COMP4. The monitored analog voltages are simultaneously connected to the positive inputs of both comparators, and the high threshold and the low threshold are connected to the negative inputs of both comparators, respectively.

By enabling the COMP1/3\_ CSR.WINMODE bit, the positive inputs of the COMP1 and COMP2, or COMP3 and COMP4 comparators can be connected together, saving an I/O pin.

For example, when WINMODE of Comparator 1 is set to 1, the positive input of the comparator will be connected to COMP2\_INP, and when WINMODE is cleared to 0, the positive input of the comparator will be connected to COMP1\_INP. Doing so can save an IO pin.

Figure 17-4 Window comparator

### 17.2.7 Hysteresis function of COMP

The comparator has a programmable hysteresis to avoid false output jumps in the presence of noisy signals. By enabling the HYST bits of COMP1\_CSR, COMP2\_CSR, COMP3\_CSR, and COMP4\_CSR, the hysteresis function of COMP1, COMP2, COMP3, and COMP4, respectively, can be turned on.

Figure 17-5 Hysteresis schematic diagram of comparator

### 17.2.8 Power Consumption Mode of COMP

The power consumption and transmission delay of the comparator can be adjusted to achieve specific applications. This function is selected by the PWRMODE [1: 0] bits of the COMPx\_CSR register.

### 17.2.9 Low Power Mode of COMP

| Mode                     | Description                                                                                          |
|--------------------------|------------------------------------------------------------------------------------------------------|
| Sleep Mode               | There was no effect on COMP.<br>The comparator interrupt may cause the device to exit sleep mode     |
| Low power operating mode | No effect                                                                                            |
| Low power sleep mode     | No impact.<br>The comparator interrupt may cause the device to exit a low-power sleep mode           |
| Stop mode                | There was no effect on COMP.<br>The comparator interrupt may cause that device to exit the stop mode |
| Standby mode             | The COMP register is powered down and must be reinitialized after exiting standby mode               |

#### 17.2.10 Interruption of COMP

The output of the comparator is connected to the EXTI controller (Extended interrupts and events) inside the chip. Each comparator has its own EXTI line and is capable of generating interrupts or events. The same mechanism is used as a low power wake-up.

TIMx registers

## 18. Operational amplifier (OPA)

### 18.1 Overview

There are 3 op amps embedded, each with two inputs and one output. Three I/Os can be connected to external pins, enabling any type of external interconnection. Operational amplifiers can be internally configured as programmable gain amplifiers, as an amplifier with forward gains ranging from 2 to 32 and inverting gains ranging from -1 to -31.

The positive input can be connected to an internal DAC. The output is connected to the internal ADC.

#### 18.1.1 Main features

- Rail-to-rail input and output voltage ranges
- Low input bias current
- Low input offset voltage
- High frequency gain bandwidth
- High speed mode for better conversion rates

#### 18.1.2 CAN block diagram

Figure 18-1 OPA module block diagram

## 18.2 OPA functional description

There are multiple modes of OPA. Each OPA can be enabled individually and the output is high impedance when disabled.

### 18.2.1 The OPA output redirects to the internal ADC channel

By setting the OPAINTOEN bit in the OPAX\_CSR register, the op amp output can be internally redirected to the ADC channel. In this case, the GPIO mapped to OPAX\_VOUT is released and may be used for other purposes. The ADC may measure the OPAX\_VOUT voltage internally.

### 18.2.2 OPA reset and clocks

The OPA clock provided by the RCC is synchronized with the PCLK2 (APB2 clock). A clock enable control bit is provided in the RCC controller. The OPAX\_CSR.OPAEN bit is used to enable and disable the OPA module. If the OPA register configuration needs to be changed, it must be before enabling the OPAEN bit to avoid impact on the output. When the output of the op amp is no longer needed, the OPA can be disabled to save power consumption. When OPA is disabled, all previously set configurations are retained.

### 18.2.3 Initial configuration

Under the default configuration conditions, OPA will be in normal operation mode using standard performance. Setting OPAX\_CSR.OPAHSM will cause OPA to switch to high-speed mode and get a better conversion rate. By default, three input/output signals of OPA are connected to external pins.

Once the OPAEN bit in the OPAX\_CSR register is set, OPA works. The two input pins and output pins are connected as shown in the table below and the default connection settings can also be changed.

Note: The input and output pins must be configured in analog mode (default state) in the corresponding GPIOx\_MODER register.

### 18.2.4 Signal connection

The connection of the op amp pins is determined by the OPAX\_CSR register. The connection of 3 operational amplifiers (OPAx, x = 1 ... 3) is described in the table below.

Table 18-1 Possible Connections of Operational Amplifier

| Signal      | IO pin                                                                         | Internal             | Comment                                    |
|-------------|--------------------------------------------------------------------------------|----------------------|--------------------------------------------|

| OPA3 output | PB1                                                                            | ADC2_IN18, ADC3_IN13 | Controlled by OPA3_INTTOEN                 |

## 18.3 OPA mode

Both the inputs and outputs of the op amp are accessible via the GPIO. The op amps can be used in a variety of configuration environments:

- Independent mode (external gain setting mode)
- PGA mode (programmable gain amplifier mode)

### 18.3.1 Independent mode (external gain setting mode)

Starting first with the OPAX\_CSR default value and the GPIOx\_MODER default state, once the OPAX\_CSR.OPAEN bit is set, the two input pins and the output pins are connected to the op amp.

This default configuration causes OPA to run in normal mode. OPA can modify the configuration through the following process:

- By setting OPAX\_CSR.OPAHSM, OPA is set to the op amp high speed mode to obtain a high conversion rate.

OPA standalone mode configuration process:

- 1) Configure OPAX\_CSR.VP\_SEL/OPAX\_CSR.VM\_SEL Select VINP/VINM
- 2) Configure the OPAX\_CSR.INTOEN bit to enable OPAX\_VOUT\_EXT
- 3) The voltage is output to OPAX\_VOUT\_EXT as long as the OPAX\_CSR.OPAEN bit is configured

Figure 18-2 Independent mode (external gain setting mode)

### 18.3.2 Programmable gain amplifier mode

OPA programmable gain amplifier mode configuration process:

- 1) Configure the OPAX\_CSR.VM\_SEL bit to 2'b10 and connect the feedback resistor to the input of OPAX\_VINM
- 2) Configure the OPAX\_CSR.PGA\_GAIN bits to 5'b00000~5'b00101 so that the internal gain is 2, 4, 8, 16 or 32
- 3) Configure the OPAX\_CSR.VP\_SEL bit to 2'b00 and connect the input of the corresponding GPIO to the OPAX\_VINP terminal
- 4) Configure the OPAX\_CSR.INTOEN bit to enable OPAX\_VOUT\_EXT or OPAX\_VOUT\_INT

- 5) As long as the OPAX\_CSR.OPAEN bit is set, the voltage on the OPAX\_VINP pin is amplified according to the selected gain and is visible on the OPAX\_VOUT\_EXT or OPAX\_VOUT\_INT pin.

Note: To avoid saturation, the input voltage must be kept below VCCA divided by the selected gain.

Figure 18-3 PGA mode, internal gain setting (x2/x4/x8/x16/x32) reverse input not used

### 18.3.3 Programmable gain amplifier mode with external filtering

OPA programmable gain amplifier mode configuration process with external filtering:

- 1) Configure the OPAX\_CSR.VM\_SEL bit to 2'b10 so that the feedback resistor is connected to the input of OPAX\_VINM.
- 2) Configure the OPAX\_CSR.PGA\_GAIN bits to 5'b10000 ~ 5'b10101 so that the internal gain of the filtered VINM < 0 > pin is 2, 4, 8, 16 or 32.
- 3) Configure the OPAX\_CSR.VP\_SEL bit to connect the input of the corresponding GPIO to the OPAX\_VINP.
- 4) Configure the OPAX\_CSR.INTOEN bit to enable OPAX\_VOUT\_EXT.
- 5) As long as the OPAX\_CSR.OPAEN bit is configured, the voltage on the OPAX\_VINP pin is amplified according to the selected gain and is visible on the OPAX\_VOUT\_EXT pin.

Any external connection on the VINM can be used in parallel with the internal PGA, for example, a capacitor can be connected between OPA\_OUT and the VINM for filtering purposes.

Figure 18-4 PGA mode, internal gain settings (x2/x4/x8/x16/x32) reverse input for filtering

### 18.3.4 Programmable gain amplifier, forward or inverting mode with external bias

OPA forward or inverting mode configuration process with external bias:

- 1) Configure the OPAX\_CSR.VM\_SELbit to 2'b10so that the feedback resistor is connected tothe input ofOPAX\_VINM
- 2) The OPAX\_CSR.PGA\_GAIN bits are configured to be 5'b01000to 5'b01101such thatthe reverse gain at the VINM < 0 >terminal is- 1, - 3, -7,-15,-31/non-reverse gain of 2, 4, 8, 16, 32
- 3) Configure the OPAX\_CSR.VP\_SELbit to connectthe input of thecorrespondingGPIOto the OPAX\_VINP
- 4) Configure the OPAX\_CSR.INTOEN bitto enableOPAX\_VOUT\_EXTorOPAX\_VOUT\_INT
- 5) As long as the OPAX\_CSR.OPAEN bit isset,the voltageon the OPAX\_VINP pin is amplified according to the selectedgainand isvisibleon the OPAX\_VOUT\_EXTorOPAX\_VOUT\_INT pin.

Figure 18-5 PGA mode, non-reverse gain setting (x2/x4/x8/x16/x32) or reverse gain setting (x-1/x-3/x-7/x-15/x-31)

### 18.3.5 Programmable gain amplifier, forward with external bias or inverted mode with filtering

OPA forward with external bias or inverted mode with filtering configuration process:

- 1) Configure the OPAx\_CSR.VM\_SELbit to 2'b10 and connect the feedback resistor to the input of OPAx\_VINM
- 2) Configure the OPAx\_CSR.PGA\_GAIN bits to 5'b11000~ 5'b11101 so that the reverse gain on the filtered VINM < 0 > and VINM < 1 > pins is -1, -3, -7, -15, -31 / the non-reverse gain is 2, 4, 8, 16, 32
- 3) Configure the OPAx\_CSR.VP\_SELbit to connect the corresponding GPIO input to the OPAx\_VINP
- 4) Configure the OPAx\_CSR.INTOEN bit to enable OPAx\_VOUT\_EXT
- 5) As long as the OPAx\_CSR.OPAEN bit is configured, the voltage on the OPAx\_VINP pin is amplified according to the selected gain and is visible on the OPAx\_VOUT\_EXT pin.

Any external connection on VINM < 1 > can be used in parallel with the internal PGA, for example, a capacitor can be connected between OPA\_OUT and VINM < 1 > for filtering purposes.

Figure 18-6 PGA mode, non-inverted gain setting (x2/x4/x8/x16/x32) or inverted gain setting (x-1/x-3/x-7/x-15/x-31) for filtering

Figure 18-7 configuration example

### 18.3.6 Current sampling mode

In motor applications, you can choose the common mode voltage built-in, and the built-in voltage can be selected as  $V_{CC}/2$  and  $V_{CC}/5$ . An external voltage may also be used.

However, common mode voltage external and built-in modes cannot exist at the same time.

Select the external voltage when  $OPA_x\_VBSEL = 0$  in the  $OPA_x\_CSR$  register.

Selecting the built-in voltage by configuring  $OPA_x\_VBSEL = 1$  in the  $OPA_x\_CSR$  register;

The built-in voltage selection  $V_{CC}/2$  or  $V_{CC}/5$  of  $OPA_x$  is controlled by configuring  $OPA\_VBIAS$  in the  $OPA1\_CSR$  register.

Note: In current sampling mode, OPA input and output need to use external input/output, that is, internal signal cannot be used as OPA input.

Figure 18-8 Current sampling circuit

## 18.4 OPA PGA Gain

When the OPA is configured in PGA mode, the gain is programmable to x2, x4, x8, x16, x32 in the forward configuration and x-1, x-3, x-7, x-15, x-31 in the inverted configuration.

When the OPA is configured in forward mode, the gain depends only on the internal resistance divider.

When configured in inverted mode, the gain factor defines not only the on-chip feedback resistance but also the signal source output impedance. If the output impedance of the signal source is not negligible compared to the input feedback resistance of the PGA, a gain error will occur.

## 18.5 Timer Control OPA VINP/VINM Select Mode

The selection of OPA inverting and non-inverting inputs can be done automatically. This automatic switching is triggered by either the TIM1 CC6 or TIM8 CC6 output arriving at the OPA input multiplexer. This is useful for dual-motor controls that require simultaneous measurement of three-phase currents on the first motor and the second motor.

Enable the automatic switch by setting the OPAx\_TCMR.TxCM\_EN bit (x = 1, 8). Inverting and non-inverting input selections are configured via OPAx\_TCMR.VPS\_SEL and VMS\_SEL. If the TxCM\_EN bit is cleared, completion is selected using VP\_SEL and VM\_SEL in OPAx\_CSR.

Figure 18-9 timer-controlled multiplexer mode

## 18.6 OPA low-power modes

Table 18-2 Effect of Low Power Mode on OPA

| Mode            | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| Sleep           | No effect                                                                              |
| Low-power run   | No effect                                                                              |
| Low-power sleep | No effect                                                                              |
| Stop0/Stop1     | OPA register value holds, OPA does not work                                            |
| Standby         | The OPA register is powered down and must be reinitialized after exiting Standby mode. |

## 19. Advanced Timer (TIM1 and TIM8)

### 19.1 Introduction

The advanced control timers (TIM1, TIM8) consist of a 16-bit auto-load counter driven by a programmable prescaler. It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion). Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers. The advanced-control (TIM1) and general-purpose (TIMx) timers are completely independent, and do not share any resources. They can be synchronized together.

#### 19.1.1 TIM1/TIM8 Main Features

The functions of the TIM1 timer include:

- 16-bit up, down, up/down auto load counter
- 16-bit programmable (can be modified in real time) prescaler, the frequency division coefficient of the counter clock frequency is any value between 1 and 65536
- Up to 6 independent channels:
  - Input capture (5/6 channel not supported)
  - Output compare
  - PWM generation (edge or middle alignment mode)
  - One-pulse mode output
- Complementary output with programmable dead time
- Synchronization circuit for controlling timer and interconnection between timer by external signal
- Allows the repetition counter of the timer register to be updated after a specified number of counter cycles
- The two brake input signals can put the timer output signal into a reset state or a known state
- An interrupt/DMA occurs when the following events occur:
  - Update: Counter upflow/downflow, counter initialization (via software or internal/external trigger)
  - Trigger event (counter starts, stops, initializes or counts by internal/external triggers)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoders and Hall sensor circuits for positioning
- Trigger input for external clock or cycle-by-cycle current management

## 19.1.2 CAN block diagram

## 19.2 TIM1/TIM8 function description

### 19.2.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The clock of the counter may be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time base unit comprises:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Autoload Register (TIMx\_ARR)
- Repetition Register (TIMx\_RCR)

An autoloader register is preloaded, and a write or read autoloader register will access its preload register. The contents of the preload register are transferred to the shadow register either immediately or at each update event (UEV), depending on the setting of the Autoload preload enable bit (ARPE) in the TIMx\_CR1 register. An update event occurs when the counter reaches an overflow condition (overflow

or underflow) and when the UDIS bit in the TIMx\_CR1 register is equal to 0. The update event may also be generated by software and other conditions. The generation of update events under each configuration will be described in detail later.

The counter is driven by the clock output CK\_CNT divided by the prescaler, which is valid for the counter only when the counter enable bit (CEN) in the TIMx\_CR1 register is set. (See the description of the slave mode controller for more details on enabling counters).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR register.

### Prescaler description

The prescaler can divide the clock frequency of the counter by any value between 1 and 65536. It is a 16-bit counter controlled based on a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescalation parameters will be adopted when the next update event comes.

The following figures give examples of changing counter parameters when the prescaler is running.

Figure 19-1 Timing diagram of the counter when the parameters of the prescaler change from 1 to 2

Figure 19-2 Timing diagram of the counter when the parameter of the prescaler is changed from 1 to 3

## 19.2.2 Counter mode

### Upcounting mode

In the count-up mode, the counter counts from 0 to the auto-load value (the content of TIMx\_ARR), then counts from 0 again and generates a count overflow event.

If a repetition counter is used, the update event (UEV) will not be generated until the number of overflows reaches the value of the configured repetition count register plus one (i.e. TIMx\_RCR+1); If a repetition counter is not used (i.e., TIMx\_RCR = 0), an update event will be generated every time the count overflows.

Setting the UG bit in the TIMx\_EGR register (either by software or using a slave mode controller) can also generate an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. No update event will be generated until the UDIS bit is cleared '0'. Even so, when an update event should occur, the counter is still cleared '0', and the counter inside the prescaler is also cleared '0' (but the value of the prescaler remains unchanged).

Furthermore, if the URS bit in the TIMx\_CR1 register is set (select the update request source), an update event UEV can be generated by setting the UG bit, but the UIF flag bit will not be set (i.e., no interrupt or DMA request will be generated). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all of the following registers are updated, and the hardware sets an update flag bit (UIF bit in the TIMx\_SR register) at the same time (according to the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register.
- The auto-load shadow register is updated with the preload value (TIMx\_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 19-3 Counter timing diagram, internal clock divided by 1

Figure 19-4 Counter timing diagram, internal clock divided by 2

Figure 19-5 Counter timing diagram, internal clock divided by 4

Figure 19-6 Counter timing diagram, internal clock divided by N

Figure 19-7 Counter timing diagram, update event when ARPE=0 (no TIMx\_ARR preloaded)

Figure 19-8 Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)

### Downcounting mode

In down-count mode, the counter starts from the auto-loaded value (the contents of TIMx\_ARR) and counts down to 0, then restarts from the auto-loaded value and generates a count underflow event.

If a repetition counter is used, the update event (UEV) will not be generated until the number of underflows reaches the value of the configured repetition count register plus one (i.e. TIMx\_RCR+1); If a repetition counter is not used (i.e., TIMx\_RCR = 0), an update event will be generated every time the count underflows.

Setting the UG bit in the TIMx\_EGR register (either by software or using a slave mode controller) can also generate an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. Even then, when an update event should

occur, the counter will restart counting from the current autoloader value while the counter inside the prescaler is cleared '0' (but the prescaling factor remains unchanged).

In addition, if the URS bit in the TIMx\_CR1 register is set (select the update request source), an update event UEV can be generated by setting the UG bit, but the UIF flag bit is not set (i.e., no interrupt or DMA request will be generated), in order to avoid clearing the counter when a capture event occurs, and generating both an update and a capture interrupt.

When an update event occurs, all of the following registers are updated, and the hardware sets an update flag bit (UIF bit in the TIMx\_SR register) at the same time (according to the URS bit):

- The repetition counter is reloaded as the contents of the TIMx\_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register).

Note: The autoloader value is updated before the counter is reloaded, so the next cycle will be the expected value.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 19-10 Counter timing diagram, internal clock divided by 2

Figure 19-11 Counter timing diagram, internal clock divided by 4

Figure 19-12 Counter timing diagram, internal clock divided by N

Figure 19-13 Counter timing diagram, update event when repetition counter is not used

### Central alignment mode (up/down count)

In central alignment mode, the counter starts counting from 0 to the auto-loaded value (TIMx\_ARR register) minus 1, generating a counter overflow event, and then counts down to 1 and generating a counter underflow event; Then re-count from 0 again.

The center alignment mode can be obtained by configuring the CMS bit in the TIMx\_CR1 register not to be '00'. The output comparison flag bit with the channel configured as output mode is set during the following counting processes: when counting down (center alignment mode 1, CMS = '01'), when counting up (center alignment mode 2, CMS = '10'), and when counting up and down (center alignment mode 3, CMS = '11').

In this mode, the DIR direction bit in the TIMx\_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. The counter then starts counting again from 0, and the prescaler internal counter also starts counting again from 0.

Setting the UDIS bit in the TIMx\_CR1 register can disable the update event. This is to avoid updating the shadow registers while writing new values in the preload registers. Although no update event will occur until the UDIS bit is cleared to 0, the counter will continue to count up or down based on the value of the current auto-reload.

Furthermore, if the URS bit in the TIMx\_CR1 register is set (select the update request source), by setting the UG bit, an update event UEV will be generated but the UIF flag will not be set (thus no interrupts and DMA requests are generated), in order to avoid clearing the counter when a capture event occurs, while generating both an update and a capture interrupt.

When an update event occurs, all registers are updated and (according to the setting of the URS bit) an update flag bit (UIF bit in the TIMx\_SR register) is also set:

- The repetition counter is reloaded with the content of TIMx\_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note: If an update occurs due to a counter overflow, the automatic reload will be updated before the counter is reloaded, so the next cycle will be the expected value (the counter is loaded as a new value).

Here are some examples of how the counter operates at different clock frequencies:

Figure 19-14 Counter timing diagram, internal clock division factor is 1, TIMx\_ARR = 0x6

Figure 19-15 Counter timing diagram, internal clock divided by 2

Figure 19-16 Counter timing diagram, internal clock division factor is 4, TIMx\_ARR = 0x36

Figure 19-17 Counter timing diagram, internal clock divided by N

Figure 19-18 Counter timing diagram, update event with ARPE=1 (counter underflow)

Figure 19-19 Counter Timing Chart, Update Event (Counter Overflow) at ARPE = 1

### 19.2.3 Repetition counter

The "Time Base Unit" explains how an update event (UEV) occurs when the counter overflows/underflows, in fact it can only occur when the repetition counter count reaches 0. This feature is very useful for generating PWM signals.

This means that data is transferred from the preload register to the shadow register (TIMx\_ARR auto-reload register, TIMx\_PSC preload register, and capture/compare register TIMx\_CCRx in comparison mode) only every N+1 count overflow or underflow, N being the value in the TIMx\_RCR repeat count register.

The repetition counter is decremented when either of the following conditions is true:

- Each time the counter overflows in up-count mode,
- Each time the counter underflows in down-count mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

The central alignment modelimits the maximum cycle period of the PWM to 128(TIMx\_RCRis an 8-bit counter), but it is able to update the duty cycle twice per PWM cycle.

The repetition counter is automatically reloaded and the repetition rate is defined by the value of the TIMx\_RCR register. When the update event is generated by software (by setting the UG bit in TIMx\_EGR) or by the slave mode controller of hardware, the update event occurs immediately regardless of the value of the repetition counter, and the contents of the TIMx\_RCR register are reloaded to the repetition counter.

Figure 19-20 Examples of update rates in different modes, and register settings for TIMx\_RCR

#### 19.2.4 External trigger input

The timer external trigger input tim\_etr can be used to:

- External clock
- From the trigger of the pattern
- As a PWM reset input in periodic current regulation

#### 19.2.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode 1: External input pins (TI1 and TI2)
- External clock mode2: external trigger input ETR
- Internal Trigger Input (ITRx): Uses one timer as a prescaler for the other. For example, one timer Timer1 may be configured as a prescaler for another timer Timer2.
- Encoder Mode

### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS = 0000), the CEN, DIR (TIMx\_CR1 register), and UG bits (TIMx\_EGR register) are de facto control bits and can only be modified by software (the UG bits are still automatically cleared). As long as the CEN bit is written as '1', the clock of the prescaler is provided by the internal clock CK\_INT.

The diagram below shows the operation of the control circuit and up counter in general mode, without the prescaler.

Figure 19-21 Control circuit in normal mode, internal clock divided by 1

### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 19-22 TI2 Example of external clock connection

For example, to configure the counter to count up on the rising edge of the TI2 input, use the following steps:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure IC2F [3: 0] of the TIMx\_CCMR1 register and select the input filter bandwidth (if no filter is needed, keep IC2F = 0000);

3. Select rising edge polarity by writing CC2P=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=00110 in the TIMx\_SMCR register;
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge of TI2 and the actual clock of the counter depends on the synchronization circuit at the input of TI2.

Figure 19-23 Control circuit in external clock mode 1

### External clock source mode 2

This mode is selected by making ECE = 1 in the TIMx\_SMCR register, and the counter can externally trigger each rising or falling edge of the ETR to count.

The following figure is a block diagram of the external trigger input:

Figure 19-24 External trigger input block diagram

For example, to configure an up-counter that counts every 2 rising edges under ETR, use the following steps:

1. No filter is needed in this example, set ETF [3:0] = 0000 in the TIMx\_SMCR register;
2. Set the prescaler and set ETPS [1:0] = 01 in the TIMx\_SMCR register;
3. Select the rising edge of the ETR input terminal and set ETP = 0 in the TIMx\_SMCR register;
4. Turn on external clock mode 2 and write ECE = 1 in the TIMx\_SMCR register;
5. Start counter, write CEN = 1 in TIMx\_CR1 register;

The counter counts at every 2 ETR rising edges.

The delay between the rising edge of the ETR and the actual clock of the counter depends on the synchronization circuit of the ETRP signal.

Figure 19-25 Control circuit in external clock mode 2

### 19.2.6 Capture/Compare channels

Each capture/compare channel is surrounded by a capture/compare register (including a shadow register), including an input portion of the capture (digital filtering, multiplexing and prescaler, except for channels 5 and 6), and an output portion (comparator and output control).

The following figures are capture/compare channel overviews.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. An edge monitor with polarity selection then generates a signal (TIxFPx) that can be triggered as an input from the slave mode controller or as a capture control. It is prescaled before the capture register (ICxPS).

Figure 19-26 Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 19-27 Capture/Compare the main circuit of channel 1

Figure 19-28 Output stage of capture/compare channel (channel 1 to 4)

Figure 19-29 Output stage of capture/compare channel (channel 5,6)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 19.2.7 Input capture mode:

In input capture mode, when the corresponding edge on the ICx signal is detected, the current value of the counter is latched into the capture/compare register (TIMx\_CCRx). When a capture event occurs, the corresponding CCxIF flag (TIMx\_SR register) is set to 1, and if an interrupt or DMA operation is enabled, an interrupt or DMA request will be generated. If the CCxIF flag is already high when the capture event occurs, the over-capture flag CCxOF (TIMx\_SR register) is set to 1. The CCxIF can be cleared by writing CCxIF = 0, or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1input rises. To do this, use the following procedure:

- Select valid input: TIMx\_CCMR1 must be connected to the TI1 input, so CC1S = 01 written in the TIMx\_CCMR1 register, as long as CC1S is not '00', the channel is configured as input, and the TIMx\_CCR1 register becomes read-only.
- Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register)). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the valid transition edge of the TI1 channel and write CC1P = 0 (set to rising edge) in the TIMx\_CCER register.
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If desired, the associated interrupt request may be allowed by setting the CC1IE bit in the TIMx\_DIER register, or the DMA request may be allowed by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- The CC1IF flag bit is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 19.2.8 PWM input mode

This mode is a special case of the input capture mode, and the rest of the operation is the same as the input capture mode except for the following differences:

- Both ICx signals are mapped to the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the cycle (TIMx\_CCR1 register) and the duty cycle (TIMx\_CCR2 register) of the PWM signal input to TI1 as follows

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P bit to '0' (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2Pbit to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

Figure 19-30 PWM input mode timing

Because only TI1FP1 and TI2FP2 are connected to the slave mode controller, the PWM input mode can only use the TIMx\_CH1/TIMx\_CH2 signal.

### 19.2.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compares signal(OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

Set the corresponding OCxM = 0101 in the TIMx\_CCMRx register to force the output comparison signal (OCxREF/OCx) to an active state. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx\_CCMRx register. Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 19.2.10 Output compare mode

This function is used to control an output waveform or indicate that a given period of time has expired. Channels 1 through 4 can output, but channels 5 and 6 are only used internally in the MCU (e.g. for generating mixed waveforms or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- If the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register selects the DMA request function), a DMA request is generated.

You can select whether the TIMx\_CCRx register needs to use a preload register by configuring the OCxPE bit in TIMx\_CCMRx.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity

– Write CCxE = 1 to enable the output

5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated by software at any time to control the output waveform, provided the preload register is not used (OCxPE = '0', otherwise the shadow register of TIMx\_CCRx can only be updated when the next update event occurs). An example is given in the figure below.

Figure 19-31 Output comparison mode, flip OC1

### 19.2.11 PWM mode

The pulse width modulation mode may produce a signal whose frequency is determined by the TIMx\_ARR register and whose duty cycle is determined by the TIMx\_CCRx register.

The OCxM bit in the TIMx\_CCMRx register is written to '0110' (PWM mode 1) or '0111' (PWM mode 2), and each OCx output channel can be independently set to generate a PWM. The corresponding preload register must be enabled by setting the OCxPE bit of the TIMx\_CCMRx register, and finally the ARPE bit of the TIMx\_CR1 register to enable the preload register that is automatically reloaded (in up-count or centrosymmetric mode).

The preload register can only be transferred to the shadow register when an update event occurs, so the user must initialize all registers by setting the UG bit in the TIMx\_EGR register before the counter starts counting.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx\_CCER and TIMx\_BDTR registers). Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

#### PWM edge-aligned mode

##### ■ Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the comparison value in TIMx\_CCRx is greater than the auto-reload value (TIMx\_ARR), OCxREF remains '1'. If the comparison value is 0,

then OCxREF remains '0'. Figure below shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

Figure 19-32 Edge-aligned PWM waveforms (ARR=8)

#### ■ Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high.

In PWM mode 1, the reference signal OCxRef is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the comparison value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, OCxREF remains '1'. 0% PWM is not possible in this mode.

#### PWM Central Alignment Mode

The center alignment mode is when the CMS bit in the TIMx\_CR1 register is not '00' (all other configurations of the CMS bit have the same effect on the OCxREF/OCx signal). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software.

The following figure gives some examples of centrally aligned PWM waveforms

- TIMx\_ARR = 8
- PWM mode is the PWM mode 1
- CMS = 01 for the TIMx\_CR1 register, in center alignment mode 1, the compare flag is set when the counter counts down.

Figure 19-33 Centre-aligned PWM waveform (APR = 8)

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx\_CR1 register. Also, do not modify the DIR and CMS bits simultaneously through software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:

-If the value of the write counter is greater than the value of the auto-reload (TIMx\_CNT > TIMx\_ARR), the direction is not updated.

For example, if the counter was counting up, it continues to count up.

-If a value of 0 or TIMx\_ARR is written to the counter, the direction is updated, but no update event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### Jitter mode

The DITHEN bit of the TIMx\_CR1 register may be enabled to turn on the jitter mode to improve the effective resolution of the PWM mode. Can be applied to CCR (improved duty cycle resolution) and ARR (improved resolution of PWM frequency)

The principle of operation is to make the actual CCR (or ARR) value change slightly (with or without increasing a timer cycle) over 16 consecutive PWM cycles, and how the change can be set by predefined settings. When calculating the average duty cycle, you can achieve a 16-fold increase in resolution. The figure below shows the jitter principle of four consecutive PWM periods

Figure 19-34 jitter principle

When jitter mode is enabled, the value of the register will automatically change as follows:

- The lowest 4 bits is the encoding for improving resolution (fractional part)
- The high bit is shifted left to 19: 4 for encoding as the base value (integer part)

Note: When dither mode is on or off, the values of ARR and CCR are automatically updated (for example, ARR = 0x05 when DITHEN = 0, then ARR = 0x50 when DITHEN = 1), the following steps must be followed when resetting the DITHEN bit

1. CEN and ARPE bits must be reset
2. The ARR [3: 0] bit must be reset
3. The DITHEN bit must be reset
4. The CCIF flag must be cleared
5. CEN bit can be set (ARPE = 1 can be set)

Figure 19-35 Data mapping and register coding in dither mode

The minimum frequency is calculated as follows:

$$\text{According to resolution} = \frac{\text{定时器频率}}{\text{PWM 频率}} \quad \text{push out: minimum PWM frequency} = \frac{\text{定时器频率}}{\text{最大分辨率}}$$

$$\text{In jitter-free mode: Minimum PWM frequency} = \frac{\text{定时器频率}}{65536}$$

$$\text{When there is jitter mode: minimum PWM frequency} = \frac{\text{定时器频率}}{65535 + \frac{15}{16}}$$

Note: The maximum values of TIMx\_arr and TIMxCCRy in jitter mode are limited to 0xFFFFEF (corresponding to 65534 in the integer part and 15 in the jitter part). Exceeding 0xFFFFEF, there will be an overflow situation, that is, arr = 0xFFFF+1 = 0.

The figure below shows that in jitter mode, the resolution of the PWM can be improved regardless of the PWM frequency

Figure 19-36 PWM Resolution VS Frequency

The duty cycle and cycle changes in 16 consecutive cycles are as follows:

Figure 19-37 PWM Jitter Mode

The auto-reload and compare value increments are distributed in a specific pattern as described in the following table, with the incremental distribution of the jitter sequence as uniformly as possible, minimizing the overall ripple

Table 19-1 CCR and ARR register jitter changes

| LSB value | PWM Cycle |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|           | 1         | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| 0000      |           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0001      | +1        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0010      | +1        |    |    |    |    |    |    |    | +1 |    |    |    |    |    |    |    |
| 0011      | +1        |    |    |    | +1 |    |    |    | +1 |    |    |    |    |    |    |    |
| 0100      | +1        |    |    |    | +1 |    |    |    | +1 |    |    |    | +1 |    |    |    |
| 0101      | +1        |    | +1 |    | +1 |    |    |    | +1 |    |    |    | +1 |    |    |    |
| 0110      | +1        |    | +1 |    | +1 |    |    |    | +1 |    | +1 |    | +1 |    |    |    |
| 0111      | +1        |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |    |    |
| 1000      | +1        |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |
| 1001      | +1        | +1 | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |
| 1010      | +1        | +1 | +1 |    | +1 |    | +1 |    | +1 | +1 | +1 |    | +1 |    | +1 |    |

The dither mode can also be applied in the intermediate alignment PWM mode (CMS! = 00). The figure below considers the case where the dither mode is applied to 8 consecutive cycles when counting up and down.

Figure 19-38 Effect of jitter on duty cycle in aligned PWM mode in middle of the figure

Table 19-2 Change of CCR Register Jitter in Middle Aligned PWM Mode

| LSB value | PWM Cycle |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

### 19.2.12 Asymmetric PWM mode

The asymmetric mode allows two centrally aligned PWM signals to produce a programmable phase shift. When the frequency is determined by TIMx\_ARR and the duty cycle and phase shift are determined by a pair of TIMx\_CCRx registers. The asymmetric mode allows the generation of two center-aligned PWM signals using programmable phase shifts. One TIMx\_CCRx register is controlled during the up-count phase and the other during the down-count phase so that the PWM can be adjusted every half PWM cycle

- The OC1REFC(orOC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- The OC3REFC(orOC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

By writing 1110 to OCxM (asymmetric PWM mode 1) and 1111 to OCxM (asymmetric PWM mode 2), asymmetric PWM mode can be independently selected on dual channels (each pair of CCR registers controls one OCx output)

Note: For compatibility reasons, the OCxM [3: 0] field is divided into two parts, with the highest and lower 3 bits not contiguous.

When a given channel is used as an asymmetric channel, its adjacent channels (channel 1 adjacent to channel 2) can also be used. For example, if OC1REFC is generated by channel 1 (asymmetric PWM mode 1), channel 2 may also output OC2REF, or OC2REFC through asymmetric PWM mode 1. The figure below represents an example of using asymmetric PWM mode to generate signals (channels 1 through 4 are configured as asymmetric PWM mode 2), which, together with the dead time generator, controls a full-bridge DC-DC phase shift inverter.

Figure 19-39 2 50% duty cycle phase shift PWM

### 19.2.13 Combined PWM mode

The combined PWM mode allows an edge or center aligned PWM signal to be generated by programmable delay and phase shift between pulses. The frequency is determined by the ARR and the duty cycle and delay are determined by the two CCRs. The resulting signal OCxREFC is generated by AND/OR logic between two reference PWMs

- The OC1REFC(orOC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- The OC3REFC(orOC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM modes can be independently selected on dual channels (each pair of CCR registers controls one OCx output) by writing to OCxM 1100 (combined PWM mode 1, logic OR output) and OCxM 1101 (combined PWM mode 2, logic AND output)

When a given channel is used as a combined PWM channel, its complementary channels must be configured in opposite PWM modes (e.g., one for combined PWM mode 1 and one for combined PWM mode 2).

The following figure shows an example of a combined mode generation signal, including

- Channel 1 is combined PWM mode 2
- Channel 2 is PWM Mode 1
- Channel 3 is combined PWM mode 2
- Channel 4 is PWM Mode 1

Figure 19-40 Combined PWM patterns for channel 1 and channel 3

#### 19.2.14 Three-phase PWM combination mode

The three-phase combined PWM mode allows three centrally aligned PWM signals to be generated by a single programming signal and logic in the middle of a pulse. The OC5REF is used to define the resulting combined signal. GC5C1/GC5C2/GC5C3 of TIM\_CCR5 is used to select by which reference

signal the OC5REF is combined. The final output signal OCxREFC is generated by AND logic of two reference PWM signals

- GC5C1 = 1, OC1REFC is controlled by CCR1 and CCR5
- GC5C2 = 1, OC2REFC is controlled by CCR2 and CCR5
- GC5C3 = 1, OC3REFC is controlled by CCR3 and CCR5
- Three-phase combined PWM mode can be independently selected from channels 1 to 3 via GC5C1/GC5C2/GC5C3

Figure 19-41 Three-phase PWM combination mode

The Trgo2 waveform shows how the ADC is synchronized in a given three-phase PWM signal

### 19.2.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time, and you have to adjust it depending on the devices you have connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

You can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals OCx and OCxN are controlled by a combination of the following control bits: the CCxE and CCxNE bits of the TIMx\_CCER register, the MOE, OISx, OISxN, OSSI and OSSR bits of the TIMx\_BDTR and TIMx\_CR2 registers, as detailed in the control bits of the complementary output channels OCx and OCxN with brake function. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. By configuring the DTG [7: 0] bit in the TIMx\_BDTR register, you can control the dead time generator for all channels. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

Figure 19-42 Complementary output with dead-time insertion

Figure 19-43 Dead-time waveforms with delay greater than the negative pulse

Figure 19-44 Dead-time waveforms with delay greater than the positive pulse.

When DTAE = 1, the rising edge dead time is configured by the DTG [7: 0] bit of TIMx\_BDTR, and the falling edge dead time is configured by the DTGF [7: 0] bit of TIMx\_DTR2. The writing of the DTAE needs to be before the counter is enabled. When CEN = 1, it is not allowed to modify the DTAE.

The dead time can be modified during the PWM operation through the mechanism of preloading. When the DTPE of TIMX\_DTR2 is set, the dead time configuration registers DTG [7: 0] and DTGF [7: 0] are preloaded, and the preloaded data is loaded into the cache register at the next update event.

Note: If the DTPE bit is set while the counter is enabled, new data written since the last update is discarded and the previous value is used

Figure 19-45 asymmetric dead time

#### 19.2.15.1 Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This allows you to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only OCxN is enabled (CCxE = 0, CCxNE = 1), it does not invert and becomes high immediately when OCxREF is active. For example, if CCxNP=0 then OCxN=OCxREF. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

#### 19.2.16 Using the brake function

The purpose of the brake function is to protect the power switch driven by the PWM output from the TIMER. The input to the two-way brakes is usually the fault output connected to the three-phase inverter and power stage chip. When the brake signal is active, it will immediately turn off all outputs of

the PWM and force them to a preset safe level state. Some internal events of the MCU can also be used as trigger signals to turn off the output.

There are two channels of braking events. Channel 1 includes system-level faults (clock failure, ECC, parity, etc.) and application-level faults (through input pins or built-in comparators), and can be forced to output to a preset level (whether working or idle) after a dead zone. Channel 2 contains only some application layer faults and forces the output to an invalid state.

The output enable signal and output level during braking are controlled by the following bits

- The MOE bit of TIMx\_BDTR can be enabled and turned off by software or 2-way brake event reset
- The OSSI bit of TIMx\_BDTR is used to define whether the timer also controls the output when idle, or releases control of the GPIO controller (high impedance state)
- The OISx and OISxN bits of TIMx\_CR2 are used to set the output to an invalid level regardless of the working or idle state, and the OCx and OCxN outputs cannot be set to an active level at the same time at the same time, regardless of the values of OISx and OISxN.

When exiting from reset, the brake function is turned off and the MOE is 0. The brake function can be turned on by enabling the BKE and BK2E bits of TIMx\_BDTR. The polarity of the brake input is configurable via BKP and BK2P. BKEx and BKPx can be modified simultaneously. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

MOE falling edge can be asynchronous, thus a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if you write MOE to 1 whereas it was low, you must insert a delay (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

A source of the brake channel 1;

- An external source can be connected to one of the TIMx\_BKIN pins (select GPIO and configuration registers), plus polarity selection and filtering
- The internal source contains 2 parts
  - ◆ Signal from brake comparator (tim\_brk\_cmpx)
  - ◆ From system brake request

A source of the brake channel 2;

- An external source can be connected to one of the TIMx\_BKIN2 pins (select GPIO and configuration registers), polarity selection and filtering
- Internal source from brake comparator signal (tim\_brk2\_cmpx)

The brake event may also be generated by software, and the BG and B2G bits of TIMx\_EGR may be set, with all brake sources being OR as brake inputs for tim\_brk and tim\_brk2. Figure below:

Figure 19-46 Brake and Brake 2 Circuit

Note: Asynchronous operation can only be guaranteed when there is no filtering. If filtering is turned on, a failsafe clock mode must be used to ensure that brake interrupt events are handled (e.g. using internal PLL or CSS, no filtering).

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, placing the output in an invalid state, an idle state, or releasing control of the GPIO controller (selected by the OSS1 bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx\_CR2 register as soon as MOE=0. If OSS1 = 0, the timer releases output control, otherwise the enable output is always high.
- When complementary outputs are used:
  - The output is first put into a reset state, i.e. an invalid state (depending on polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the clock of the timer still exists, the dead time generator will re-take effect, driving the output port according to the level indicated by the OISx and OISxN bits after the dead time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that the dead time is longer than usual (approximately 2 clock cycles) because of the resynchronization of the MOE.
  - if OSS1 = 0, the timer releases the output, otherwise keeps the output enabled; Or once one of CCxE and CCxNE becomes high, the enable output becomes high.
- The brake status flag is pulled up (SBIF, BIF, B2IF for TIMx\_SR). If the BIE bit in the TIMx\_DIER register is set, an interrupt is generated when the brake status flag (BIF bit in the TIMx\_SR register) is '1'. If the TDE bit in the TIMx\_DIER register is set, a DMA request is generated.
- If the AOE bit in the TIMx\_BDTR register is set, the MOE bit is automatically set again at the next

update event UEV. This can be used to perform a regulation, for instance. Otherwise, the MOE remains low until it is set to '1' again; At this time, this feature can be used in safety. You can connect the brake input to the power-driven alarm output, thermal sensor or other safety devices.

Note: When AOE is 1, if MOE is reset by the CPU, the output will enter the idle state and be forced to an invalid level or high impedance (depending on the value of OSS1). If both MOE and AOE are reset by the CPU, the output will enter the invalid state and the output level is driven by the OISx bit.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). At the same time, the status flags BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows the user to freeze several configuration parameters (dead time duration, OCx/OCxN polarity and disabled state, OCxM configuration, brake enable and polarity). The user can select one of the three levels of protection by setting the LOCK bit in the TIMx\_BDTR register, see Brake and Dead Time Register (TIMx\_BDTR). The LOCK bits can be written only once after an MCU reset.

The figure below shows an example of behavior of the outputs in response to a break.

Figure 19-47 Output behavior in response to a break

The two brake input signals have different behaviors at the output of the timer

Tim\_brk can either invalidate the output or force it to a predefined secure state

Tim\_brk2 can only make the output invalid.

The priority of `tim_brk` is higher than that of `tim_brk2`, which is described by the following figure:

Note: `tim_brk2` is only used when `OSSR = OSSl = 1` (output is not high impedance)

Table 19-3 Output Behavior at Brake and Brake 2 Input

| BRK      | BRK2   | TIM output status                                                                                         | Typical situation             |                               |
|----------|--------|-----------------------------------------------------------------------------------------------------------|-------------------------------|-------------------------------|
|          |        |                                                                                                           | OCxN output (low side switch) | OCx output (high side switch) |
| Active   | X      | -Output is invalid and force output state (after dead zone)<br>-Output forbidden if <code>OSSI = 0</code> | On after dead zone insertion  | OFF                           |
| Inactive | Active | Not valid                                                                                                 | OFF                           | OFF                           |

The following figure depicts the output behavior of `OCx` and `OCxN` when `tim_brk` and `tim_brk2` are valid. All polarities are highly effective (`CCxP = CCxNP = 0` of the `TIMx_CCER` register)

Figure 19-48 PWM output state after braking and braking 2 (`OSSI = 1`)

Figure 19-49 PWM output state after braking and braking 2 (`OSSI = 0`)

### 19.2.17 Bidirectional brake input

TIM1 has two-way brake I/O, as shown in the figure below:

Figure 19-50 Output Redirection (when Brake 2 is not requested)

I/O support features:

- Provides a board-level global brake signal that sends a fault signal to the external MCU and gate driver through a unique pin that can be used as both input and output
- When it is necessary to combine a plurality of internal and external brake sources, the internal brake source and the plurality of external open-drain sources are OR calculated as the unique trigger signal of the braking event

The inputs of `tim_brk` and `tim_brk2` are controlled to be bidirectional by the `BKBID` and `BK2BID` bits of `TIMxBDTR`. `BKBID` and `BK2BID` can be set to 1 using the `LOCK` bit (`LOCK` level 1) of `TIMxBDTR`, and the implementation is locked into read-only mode.

Both `tim_brk` and `tim_brk2` inputs can use bidirectional mode and require I/O configuration in open drain mode with low active polarity (via `BKINP`, `BKP`, `BK2INP`, `BK2P` control bits). Whether from the system (e.g. CCS), from the board-level peripheral, or the brake input forcing a low level indicates a brake input failure event, it can be used as a brake request. However, for safety reasons, when the polarity bit is not effectively configured (when configured to be active high), the bidirectional mode is disabled. Software braking events (`BG`, `B2G`) will also cause the brake I/O to be pulled down, which is used to show external devices that this timer has entered the braking state. Of course, it is only possible when `BKE` or `B2KE` is 1. When `BKE` or `B2KE` is 0, a software brake event occurs, the output is set to a safe state and a brake flag signal is generated, but it has no effect on `TIMx_BKIN` and `TIMx_BKIN2` I/O.

A safe release mechanism prevents the system from being restrictively locked (a low level at the brake input triggers a brake, which in turn forces the input to low level).

When the `BKDSRM` (`BK2DSRM`) bit is set to 1, the brake output control can be released, the fault flag signal is cleared and the possibility of reconfiguring the system is provided.

Under no circumstances should the brake protection circuit be turned off:

- The brake input path is always active: even if the `BKDSRM` (`BK2DSRM`) bit is set to 1 and the open-drain control is released, the brake event is still active. This prevents that PWM output from being restarted while still in the brake state
- When the output is enabled (`MOE` = 1), the `BKDSRM` (`BK2DSRM`) bit cannot release brake protection

Table 19-4 Brake protection status

| MOE | BKBID (BK2BID) | BKDSRM (BK2DSRM) | Brake protection status |
|-----|----------------|------------------|-------------------------|
| 0   | 0              | X                | Enable                  |
| 0   | 1              | 0                | Enable                  |
| 0   | 1              | 1                | 1 1 Disarmed            |
| 1   | X              | X                | Enable                  |

#### 19.2.17.1 Enable and re-enable the brake circuit

By default, the brake circuit (in input or bi-directional mode) is enabled

Follow the following procedure to restart the protection after braking (or brake 2):

- The BKDSRM (BK2DSRM) bit must be set to 1 to release output control
- The software must wait until the system brake status disappears and then clear the SBIF status flag (or systematically clear it before re-enabling)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by the hardware (when the application brake state disappears)

In this way, the brake circuit is activated and the MOE bit can be re-enabled for the PWM output

#### 19.2.18 Clearing the OCxREF signal on an external event

For a given channel, setting the corresponding OCxCE bit in the TIMx\_CCMRx register to '1' enables the OCxREF signal to be pulled low with a high level at the OCREF\_CLR\_INT input, and the OCxREF signal will remain low until the update event UEV generated by the next count overflow occurs. This function can only be used in output compare and PWM modes. It does not work in Forced mode. While OCREF\_CLR\_INT can be selected between OCREF\_CLR and ETRF (after ETR filtering) by configuring the OCCS bit in the TIMx\_SMCR register.

Figure 19-51 OCREF\_CLR input selection

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.

2. The external clock mode 2 must be disabled: bit ECE of the TIMx\_SMCR register set to '0'.
  3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured as needed.
- The figure below shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is placed in PWM1 mode.

Figure 19 -52OCxREF for clearing TIMx

#### 19.2.19 Generate a six-step PWM output

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. These preload bits are transferred to the shadow register when a COM commutation event occurs. In this way, you can pre-set the configuration of the next step and change the configuration of all channels at the same time. COM can be generated by software by setting the COMG bit in the TIMx\_EGR register or by hardware (on TRGI rising edge).

When a COM event occurs, a flag bit (COMIF bit in the TIMx\_SR register) will be set. At this time, if the COMIE bit of the TIMx\_DIER register has been set, an interrupt will be generated; If the COMDE bit of the TIMx\_DIER register has been set, a DMA request is generated.

The figure below describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 19-53 generates a six-step PWM, using COM example (OSSR = 1)

### 19.2.20 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV. A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- Up count mode: counter  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),
- Down counting mode: Counter  $CNT > CCRx$ .

Figure 19-54 Example of one pulse mode

For example one may want to generate a positive pulse on OC1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the TI2 input pin.

Assume TI2FP2 as the trigger:

- Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=0 in the TIMx\_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The tDELAY is defined by the value written in the TIMx\_CCR1 register.
- The tPULSE is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '0' to '1' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx\_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0) When OPM bit in the TIMx\_CR1 register is set to '0', so the repetitive mode is selected.

#### 19.2.20.1 Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations, and it limits the minimum delay tDELAY min we can get. If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx\_CCMRx register. Then OCxREF (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2mode.

#### 19.2.21 Retriggerable Single Pulse Mode

This mode allows the counter to start in response to excitation and generate pulses of programmable length, which differs from the non-retriggerable single pulse mode described in the previous section as follows:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- If a new trigger occurs before the pulse generated by the previous trigger is completed, the pulse is extended.

To use the retriggeable monopulse mode, the timer must be in slave mode, the bit SMS [3: 0] = "1000" in the TIMx\_SMCR register (combined mode-reset + trigger), and the OCxM [3: 0] bit set to "1000" or "1001" (retriggeable OPM mode 1 or 2).

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: For compatibility reasons, the OCxM [3: 0] and SMS [3: 0] bit fields are split into two parts, with the most significant bit not contiguous with the 3 least significant bit positions.

This mode must not be used in conjunction with the central alignment count mode. CMS [1: 0] = 00 must be in TIMx\_CR1.

Figure 19-55 Example of a retriggeable monopulse mode

### 19.2.22 Comparison mode generation pulse

Pulses may be generated by comparing matching events. When the counter value is equal to the given comparison value, a programmable width pulse signal is generated for debugging and synchronization purposes.

This mode can be used with any slave mode, including encoder mode. It is only available for 3/4 channels in edge and center alignment counting mode. The pulse generator is unique and shared by these two channels, as shown in the following figure:

Figure 19-56 Pulse generator circuit

The following figure shows how pulses are generated in edge counting and encoder modes:

Figure 19-57 Generate pulses by comparing events in edge alignment and center alignment modes

The output comparison mode is selected by OC3M [3: 0] and OC4M [3: 0] in TIMx\_CCMR2

The pulse width is programmed via the PW [7: 0] register, using the clock generated by clock prescaling via PWPRSC [2: 0]

$$t_{PW} = PW[7:0] \times t_{PWG}$$

$$t_{PWG} = xCK \cdot 2^{(PWPRSC[2:0] - 1)} \cdot \text{INT}$$

The resolution and maximum value depend on the value of the prescaler

Pulse re-trigger: When the pulse is output normally, a new trigger comes, which will cause the pulse to be extended

Note: If both channels are enabled at the same time, the pulses output are independent as long as the trigger on one channel does not overlap with the pulses generated by the other channel. If the two triggers overlap, the trigger 1 generation pulse will be extended (will be re-triggered), and the last trigger generation pulse width will be correct.

Figure 19-58 Generate pulses by comparing events in edge alignment and center alignment modes

## 19.2.23 Encoder interface mode

### 19.2.23.1 Quadrature encoder

To select Encoder Interface mode: write SMS='0001' in the TIMx\_SMCR register if the counter is counting on TI1 edges only, SMS=0010 if it is counting on TI2 edges only and SMS=0011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, you can program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Referring to the table below, assuming that the counter has been started (CEN = 1 in the TIMx\_CR1 register), the counter is driven by each valid jump on TI1FP1 or TI2FP2. TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx\_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together. In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 19-5 Relationship between counting direction and encoder signal (CC1P = CC2P = 0)

| Effective edge                                        | SMS [3: 0] | Reverse signal level<br>(TI1FP1 for TI2,<br>TI2FP2 for TI1) | TI1FP1 signal |         | TI2FP2 signal |         |
|-------------------------------------------------------|------------|-------------------------------------------------------------|---------------|---------|---------------|---------|
|                                                       |            |                                                             | Rising        | Falling | Rising        | Falling |
| Count only at TI1<br>single edge<br>x1 mode           | 1110       | High                                                        | Minus         | Add     | -             | -       |
|                                                       |            | Low                                                         | -             | -       | -             | -       |
| Count only at TI2<br>single edge<br>x1 mode           | 1111       | High                                                        | -             | -       | Add           | Minus   |
|                                                       |            | Low                                                         | -             | -       | -             | -       |
| Count only at TI1<br>double edge<br>x2 mode           | 0001       | High                                                        | Minus         | Add     | -             | -       |
|                                                       |            | Low                                                         | Add           | Minus   | -             | -       |
| Count only at TI2<br>double edge<br>x2 mode           | 0010       | High                                                        | -             | -       | Add           | Minus   |
|                                                       |            | Low                                                         | -             | -       | Minus         | Add     |
| Counting at TI1<br>and TI2 double<br>edges<br>x4 mode | 0011       | High                                                        | Minus         | Add     | Add           | Minus   |
|                                                       |            | Low                                                         | Add           | Minus   | Minus         | Add     |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder's differential outputs to digital signals.

This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The figure below gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = '01' (TIMx\_CCMR1 register, TI1FP1 mapped to IC1)
- CC2S = '01' (TIMx\_CCMR2 register, TI2FP2 mapped to IC2)
- CC1P = '0' (TIMx\_CCER register, TI1FP1 is not inverted, TI1FP1 = TI1)
- CC2P = '0' (TIMx\_CCER register, TI2FP2 is not inverted, TI2FP2 = TI2)
- SMS = '011' (TIMx\_SMCR register, all inputs are valid on rising and falling edges).
- CEN = '1' (TIMx\_CR1 register, counter enabled)

Figure 19-59 Example of counter operation in encoder interface mode

The following figure shows an operation example of the counter when the polarity of IC1FP1 is inverted (CC1P = '1', other configurations are the same as the above example)

Figure 19-60 IC1FP1 Inverted Encoder Interface Mode Example

The figure below shows the count value when the steering turns over in different modes:

Figure 19-61 Quadrature Encoder Counting Mode

When the timer is configured in the encoder interface mode, information of the current position of the sensor may be provided. By configuring the second timer in the capture mode, the interval between the two encoder events can be measured, and dynamic information (speed, acceleration, deceleration) can be obtained. An encoder output indicating a mechanical zero may be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. If possible, you can latch the value of the counter to the third input capture register (the capture signal must be periodic and can be generated by another timer); Its value can also be read by a DMA request generated by a real-time clock.

The UIFREMAP bit of the TIMxCR1 register forces the continuous copy of the update interrupt flag (UIF) to the highest bit of the timer counter (TIMxCNT [31]). This allows the count value and a state generated by the UIFCPY flag to be readable. This simplifies the calculation of angular velocity by avoiding causing race conditions. For example, by sharing processing between background tasks (counter readout) and interrupts (interrupt updates

There is no delay between UIF and UIFCPY flag assertions

In a 32-bit counter design, when the UIFREMAP bit is set, the 31st bit of the counter is overwritten by the UIFCPY flag when reading (the most significant bit of the counter is only accessible in write mode)

### 19.2.23.2 Clock plus directional encoder mode

In addition to quadrature encoders, the timer also supports other different types of encoder modes

**Clock plus direction mode** As shown in the figure, the clock is provided by TI2 and the direction is input by TI1, this mode is enabled by configuring the SMS [3: 0] of the TIMx\_SMCR register as follows:

- 1010: x2 mode, counter updates on rising and falling edges of clock
- 1011: x1 mode, counter is updated at one edge, rising edge is updated at CC2P = 0, falling edge is updated at CC2P = 1

The polarity of the directional signal input to TI1 is determined by the CC1P bit, CC1P = 0: positive polarity (count up when TI1 is high, count down when TI1 is low); CC1P = 1: negative polarity (count down when TI1 is high, count up when TI1 is low)

Figure 19-62 direction plus clock encoder mode

### 19.2.23.3 Directional clock encoder mode

In directional clock mode (shown in the figure below), the clock is provided by two signals, one at a time depending on the direction, thus having an up-count clock signal (T12) and a down-count clock signal (T11). This mode is enabled by configuring the SMS [3: 0] of the TIMx\_SMCR register as follows:

- 1100: x2 mode, regardless of which clock line, the counter is updated on both the rising and falling edges of the clock. The clock initial state may be configured by the CC1P and CC2P bits. CCxP = 0 represents a high level initial state and CCxP = 1 represents a low level initial state
- 1101: x1 mode, the counter is updated at one edge, depending on the values of CCx1P and CCx2P. CCxP = 0 indicates a falling edge count and the initial state is high. CCxP = 1 indicates a rising edge count and the initial state is low.

Figure 19-63 Directional Clock Encoder Mode (CC1P = CC2P = 0)

Figure 19-64 Directional Clock Encoder Mode (CC1P = CC2P = 1)

The following table details how the directional clock mode operates for any input transition:

Table 19-6 Counting direction versus encoder signals

| Effective edge      | SMS [3: 0] | Reverse signal level<br>(TI1FP1 for TI2,<br>TI2FP2 for TI1) | TI1FP1 signal |         | TI2FP2 signal |         |
|---------------------|------------|-------------------------------------------------------------|---------------|---------|---------------|---------|
|                     |            |                                                             | Rising        | Falling | Rising        | Falling |
| x2 mode<br>CCxP = 0 | 1100       | High                                                        | Minus         | Minus   | Add           | Add     |
|                     |            | Low                                                         | -             | -       | -             | -       |
| x2 mode<br>CCxP = 1 | 1100       | High                                                        | -             | -       | -             | -       |
|                     |            | Low                                                         | Minus         | Minus   | Add           | Add     |
| x1 mode<br>CCxP = 0 | 1101       | High                                                        | -             | Minus   | -             | Add     |
|                     |            | Low                                                         | -             | -       | -             | -       |
| x1 mode<br>CCxP = 1 | 1101       | High                                                        | -             | -       | -             | -       |
|                     |            | Low                                                         | Minus         | -       | Add           | -       |

#### 19.2.23.4 Index input

The counter may be reset by an index signal output by the encoder for indicating an absolute reference position. The index signal must be connected to the tim\_etr input. It may be filtered by a digital filter.

The IE bit of the TIMx\_ECR register enables the index function, and the IE bit can only be enabled in encoder mode, that is, when the SMS [3: 0] is configured to the following values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111

As shown in the figure below, commercial encoders have several options for index pulse adjustment

- Gating of A and B: The pulse width is 1/4 of a channel, aligned with the edges of A and B
- Gating of A (gating of B): The pulse width is 1/2 of a channel, aligned with the edge of A
- Ungated: Pulse width up to one channel period, not aligned with channel edge

Figure 19-65 Index gating selection

The figure below shows that the circuit can tolerate the jitter of the index signal in any gating mode. In ungated mode, the index signal pulse width needs to be strictly less than 2 encoder cycles. If greater than or equal to 2 cycles, the counter will be reset multiple times.

Figure 19-66 Index signals for jitter

The timer fully supports 3 gating modes and does not require special programming. It only needs to define what state of the encoder (the combination of channel A and channel B states) the index signal needs to be synchronized. By configuring the IPOS [1: 0] of the TIMx\_ECR register.

The detection event of the index signal varies depending on the counting direction to ensure symmetrical operation during the rotation direction flip.

- The counter is reset during up count (DIR = 0)
- When counting down, the counter value is set to TIMx\_ARR

This allows indexes to be generated at the same mechanical angular position regardless of the counting direction. The figure below shows which position indexes are generated, for a simple example (one encoder provides 4 mechanical rotations along each standard)

Figure 19-67 Index Generation at IPOS [1: 0] = 11

The following figure shows the waveform and corresponding values at IPOS [1: 0] = 11, which indicates that the moment when the counter value is forced is automatically adjusted according to the counting direction

- Counter cleared When the encoder enters 11 state (channel A = 1, channel B = 1), counting up (DIR = 0)
- The counter value is set to TIMx\_ARR when leaving the 11 state, counting down (DIR = 1)

Index detection events can generate interrupts

The arrow indicates which conversion process index event interrupt is generated

Figure 19-68 Index at IPOS [1: 0] = 11 and count values at channel A gated mode

The following figure shows the waveform and corresponding values in ungated mode, with arrows indicating which transition the index event interrupt occurred

Figure 19-69 Count values in ungated index mode at IPOS [1: 0] = 00

The following figure shows the waveforms and corresponding values in A and B gated modes, with arrows indicating which transition process index event interrupt occurs

Figure 19-70 indexes and count values when channels A and B are gated

The following two figures illustrate in detail cases where the index pulse width is less than 1/4 of the encoder period

Figure 19-71 Operation of encoder mode with narrow index pulse at IPOS [1: 0] = 11

Figure 19-72 ARR = 0x07 time-to-time narrow index pulse reset counter

The following figure shows in detail how indexes are managed in x1 and x2 schemas

Figure 19-73 IPOS [1: 0] = 01 in x1 and x2 modes

#### ■ Directional index sensitivity

You can allow the index to be valid only in the selected counting direction by configuring the IDIR [1: 0] of the TIMx\_ECR register.

The following figure shows the relationship between values, indexes, and count reset events based on IDIR [1: 0].

Note: IDIR must be written until the IE bit is reset (index mode is off)

Note: Directional index sensitivity does not support clock + directional mode, when SMS = 1010 or 1011, IDIR must be set to 00

Figure 19-74 oriented index sensitivity

#### ■ Special First Index Event Management

The FIDX bit of the TIMx\_ECR register allows indexing to be performed only once, as shown in the figure below. When the first index arrives, the subsequent indexes are ignored. If desired, the circuit can be re-enabled by writing the FIDX bit to 0 and then to 1.

Note: When FIDX = 1, if the direction changes at position 0 (index active), index may be issued twice (IDXf flag set)

Figure 19-75 Counter reset when FIDX bit is set

#### ■ Index management in non-orthogonal mode

The following two figures describe in detail how indexes are managed in directional clock mode and clock + directional mode. I.e. SMS = 1010 or 1011

In these modes, the sensitivity of the index is determined by the IPOS

IPOS [0] = 0: Detect index at low level of clock

IPOS [0] = 1: Detect index at high level of clock

IPOS [1] has no effect.

Figure 19-76 clock plus directional mode index behavior (IPOS [0] = 1)

Figure 19-77 oriented clock mode index behavior (IPOS [0] = 1)

#### Encoder Error Management

There are 2 quadrature signals in the encoder configuration that are valid, and it is necessary to detect conversion errors. The readings on the 2 inputs correspond to 2-digit Gray codes to represent the state diagram, as shown in the figure. You can only change 1 bit at a time. The erroneous transition pulls up the interrupt flag TERRF in the TIMx\_SR status register. If the TERRIE position of the TIMx\_DIER register is 1, a transition error interrupt will be generated.

Figure 19-78 Schematic diagram of orthogonal coded signal states

After the encoder has the index signal, it can detect abnormal operation that causes pulse excess during each rotation. The encoder will provide  $N$  pulses per rotation and will produce a  $4 * N$  count. The index signal resets the counter every  $4 * N$  clock cycles.

If the counter value is tapered from  $TIMx\_ARR$  to 0 or from 0 to  $TIMx\_ARR$  without an index event, this is reported as an index position error.

The overflow threshold is configured by the  $TIMx\_ARR$  register. The resulting count value of the 1000-line encoder ranges from 0 to 3999 (in 4x read mode). The overflow detection threshold must be set to  $TIMx\_ARR = 3999 + 1 = 4000$ .

When counting up, the error is asserted when the transition is delayed to 0 to 1. The figure below shows the processing of narrow index signals in A and B gated modes.

Figure 19-79 Error detection when is coded up

When counting down, the detection must be based on the previous transition from 1 to 0. The figure below shows the processing of narrow index signals in A and B gated modes. In order to avoid the encoder immediately after index detection jitter between the two values of TIMx\_ARR and 0, and erroneously generate false determination.

Figure 19-80 Error Detection when Downcoding

An index error will pull up the IERRF interrupt flag bit of the TIMx\_SR status register. If the TERRIE position of the TIMx\_DIER register is 1, a transition error interrupt will be generated.

#### ■ Functional encoder interrupt

The following interrupt are all valid in encoder mode

- ◆ **Direction change:** In encoder mode, any change in counting direction will cause the DIR bit of TIMx\_CR1 to flip, and the change in direction will pull up the DIRF interrupt flag bit of the TIMx\_SR status register. If the DIRIE bit of the TIMx\_DIER register is enabled, a change of direction interrupt is also generated
- ◆ **Index event:** The index event will pull up the IDXF interrupt flag bit of the TIMx\_SR status register. An index interrupt is also generated if the IDXIE bit of the TIMx\_DIER register is enabled

#### ■ Runtime updates encoder mode from mode preload function

It is necessary to switch from one encoder mode to another operation mode, which is usually done at high speeds to reduce the rate of update interrupts. The figure below shows switching from x4 mode to x2 mode and then switching to x1 mode.

For this purpose, SMS [3: 0] can be preloaded. The enable bit is controlled by the SMSPE bit of the TIMx\_SMCR register. The selection of the trigger signal from the SMS [3: 0] preload to the active value can be controlled using the SMSPS bit of the TIMx\_SMCR register.

- ◆ **SMSPS = 0:** Transmission is triggered by UEV, this mode must turn off the index function (IE = 0)
- ◆ **SMSPS = 1:** Transfer triggered by index event

Figure 19-81 The encoder mode is updated by preload when event updates

#### ■ Encoder clock output

The working principle of the encoder is not entirely suitable for high-resolution fast measurements. At low speeds, it requires a considerable integration time to have a sufficient number of clock edges and accurate measurements.

At low speeds, the best way is to measure the edge-to-edge clock cycle directly. You may need to use a slave timer at this time. The timer may output the clock signal of the encoder through `tim_trgo`. The slave timer may perform cycle measurements and provide speed information for each encoder clock edge.

This mode is enabled by setting `MMS[3:0] = 1000` of the `TIMx_CR2` register. And can only be used if the `SMS[3:0]` is configured to 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Other `SMS[3:0]` values are not allowed and may produce unexpected behavior.

#### 19.2.24 Directional bit output

It is also necessary to output the direction bit of the timer, which is output from the `OC3N` and `OC4` channels by configuring the `OC3M[3:0]` and `OC4M[3:0]` bit segments of the `TIMx_CCMR2` register to 1011 (copying the `DIR` bit of the `TIMx_CR1` register).

This feature is used to monitor the counting direction (or rotation direction) of the encoder, or can provide an indication signal of the upper/lower stages in the intermediate alignment PWM mode.

#### 19.2.25 UIF bit remapping

The `UIFREMAP` bit of the `TIMx_CR1` register can force a continuous copy of the UIF to the 31st bit of the timer counter (`TIMxCNT[31]`). This allows both the value of the counter and a potential rolling state exhibited by the `UIFCPY` flag signal to be read out. In special cases, this can simplify the calculation by avoiding race conditions, for example by simultaneous processing of counter readout and update interrupts.

The UIF and `UIFCPY` flags are generated without delay.

#### 19.2.26 Timer input XOR function

The `TI1S` bit in the `TIMx_CR2` register allows the input filter of channel 1 to be connected to the output of an exclusive OR gate, whose three inputs are `TIMx_CH1`, `TIMx_CH2` and `TIMx_CH3`.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature being used to connect a Hall sensor is given in the next section.

### 19.2.27 Interfacing with Hall sensors

When using an advanced control timer (TIM1 or TIM8) to generate a PWM signal to drive the motor, another general-purpose TIMx (TIM2, TIM3, TIM4 or TIM5) timer can be used as an "interface timer" to connect the Hall sensor, as shown in the figure below. The timer input pins (TI1, TI2, TI3) are connected to the TI1 input channel through an XOR gate (selected by setting the TI1S bit in the TIMx\_CR2 register), at which time the "interface timer" is used to capture this signal.

The slave mode controller is configured to reset mode, and the slave input is TI1F\_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

The capture/compare channel 1 on the "interface timer" is configured in the capture mode and the capture signal is TRC (as shown below). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The "interface timer" can be used to generate a pulse in the output mode, which can be used (by triggering a COM event) to change the properties of each channel of the advanced timer TIM1 or TIM8, while the advanced control timer generates a PWM signal to drive the motor.

Therefore, the "interface timer" channel must be programmed to generate a positive pulse after a specified delay (output comparison or PWM mode), which is sent to the advanced control timer TIM1 or TIM8 through the TRGO output.

Example: one wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Set the TI1S bit of the TIMx\_CR2 register to '1', and configure three timer inputs to logic XOR to the TI1 input;
- Program the time base: write the TIMx\_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to obtain a maximum counter period, which is longer than the time interval between two changes on the sensor);
- Set channel 1 to capture mode (select TRC): set CC1S = 01 in the TIMx\_CCMR1 register, and set a digital filter if necessary;
- Set channel 2 to PWM2 mode with the required delay: set OC2M = 111 and CC2S = 00 in the TIMx\_CCMR1 register;
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx\_CR2 register to '101'.

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx\_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx\_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step, which can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The following figure shows an example of this

Figure 19-82 Example of Hall sensor interface

### 19.2.28 Synchronization of TIMx timer and externally triggered

The TIMx timer can be synchronized with an external trigger in multiple modes: reset mode, gated mode, trigger, reset + trigger and gated + reset mode.

#### 19.2.28.1 Slave mode: Reset mode

When a trigger input event occurs, the counter and its prescaler can be re-initialized; Meanwhile, if the UDIS bit of the TIMx\_CR1 register is low, an update event UEV is also generated; All preload registers (TIMx\_ARR, TIMx\_CCRx) are then updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=0100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. At the same time, a trigger flag (TIF bit in the TIMx\_SR register) is set, and an interrupt request or a DMA request is generated according to the setting of the TIE (Interrupt Enable) bit and the TDE (DMA Enable) bit in the TIMx\_DIER register. The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 19-83 Control circuit in reset mode

#### 19.2.28.2 Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register. In gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level.

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 19-84 Control circuit in Gated mode

### 19.2.28.3 Slave mode: Trigger mode

The selected event on the input enables the counter.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Figure 19-85 Control circuit in trigger mode

### 19.2.28.4 Slave mode: reset plus trigger combination mode

In this mode, the rising edge of the trigger input initializes the counter and generates an update signal for the register, turning on the counting

This mode is used for a single pulse mode

### 19.2.28.5 Slave mode: gating plus reset combination mode

The clock of the counter is enabled only when the trigger input is high. The counter stops when the trigger signal is pulled low. The start and stop of the counter can be controlled

This mode allows detection of out-of-range PWM signals (duty cycle exceeding maximum expected value)

### 19.2.28.6 Slave mode: External clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit through the TIMx\_SMCR register:

- ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Channel 1 is configured as follows to detect the rising edge of TI1:
- IC1F = 0000: no filter
  - The capture prescaler is not used for triggering, so it does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source
  - Set CC1P = 0 in the TIMx\_CCER register to determine polarity (only rising edges are detected)
3. Set SMS = 110 in the TIMx\_SMCR register, and configure the timer to trigger mode. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.
- The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

Figure 19-86 Control Circuit in External Clock Mode 2 + Trigger Mode

### 19.2.29 DMA Burst Mode

The TIMx timer has the ability to generate multiple DMA requests when a single event occurs. The main purpose is to be able to reprogram some functions of the timer multiple times without the overhead of software. But it is also possible to read several registers in a row at fixed intervals.

The destination of the DMA controller is unique and must point to the virtual register TIMx\_DMAR. When a given timer event occurs, the timer initiates a series of DMA requests. Each write to the TIMx\_DMAR register actually redirects a timer register.

The DBL [4: 0] bit in the TIMx\_DCR register sets the DMA burst length. When a read or write access is made to a TIMx\_DMR address, the timer recognizes burst transmissions, that is, the number of transmissions (in half a word or byte)

The DBA [4: 0] bit of TIMx\_DCR defines the DMA base address for DMA transmission (when read and write operations are completed through the TIMx\_DMAR address). The DBA is defined as the offset from the TIMx\_CR1 register address.

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst characteristic is used to update the contents in the CCRx register when an update event occurs, transmitting a half-word to CCRx by DMA.

This is done through the following steps:

Configure the corresponding DMA channel as follows:

The DMA channel peripheral address is the address of the DMAR register

The DMA channel storage address is the BUFF address in RAM, which contains the data transmitted by DMA to CCRx

Number of data transferred = 3 (see note)

Polling Mode Off

Configure DCR registers by configuring DBA and DBL: DBL = 3, DBA = 0xE

Enable timer update DMA request (UDE = 1)

Enable timer

Enable the DMA channel

This example applies to the case where each CCRx register is updated once. If each CCRx is updated twice, the number of data transfers needs to be set to 6. For example, suppose that the RAM buffer contains data1, data2, data3, data4, data5 and

data6. Data is sequentially transmitted to CCRx: the first update DMA request, data1 is transmitted to CCR2, data2 is transmitted to CCR3, and data3 is transmitted to CCR4; For the second update DMA request, data4 is transmitted to CCR2, data5 is transmitted to CCR3, and data6 is transmitted to CCR4.

Note: Null values can be written to the reserved register

### 19.2.30 TIM1/TIM8 DMA Request

TIM1/TIM8 can generate DMA requests as shown in the following table:

Table 19-7 DMA Request

| DMA request source   | DMA enable control bit |
|----------------------|------------------------|
| update               | UDE                    |
| Compare/Capture 1    | CC1DE                  |
| Compare/Capture 2    | CC2DE                  |
| Comparison/Capture 3 | CC3DE                  |
| Comparison/Capture 4 | CC4DE                  |
| COM                  | COMDE                  |
| Trigger              | TDE                    |

### 19.2.31 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. See Section 20.2.22: Timer Synchronization for details.

### 19.2.32 Debug Mode

When the microcontroller enters debug mode (Cortex-M4F core stops), according to the setting of DBG\_TIMx\_STOP in the DBG module,

The TIMx counter may either continue normal operation or stop. See subsequent DBG sections for details.

Behavior in debug mode can be programmed using a dedicated configuration for each timer in the Debug Support Module (DBG)

For safety reasons, when the counter stops, the output is disabled (if the MOE is reset). The output can be forced to an invalid level (OSS1 = 1), or taken over by the GPIO controller (OSS1 = 0), typically forced to high impedance.

See DBG module description for details

### 19.2.33 TIM1/TIM8 Interrupt

| Interrupt event            | Event flag | Interrupt enable control bit |
|----------------------------|------------|------------------------------|
| update                     | UIF        | UIE                          |

| 23: 20 | MMS2 [3: 0] | RW | 4'h0 | <p>Main mode selection (Master mode selection 2)</p> <p>These four bits are used to select synchronization information (TRGO2) to send to the ADC, and possible combinations are as follows:</p> <p>0000: Reset-The UG bit of the TIMx_EGR register is used as a trigger output (TRGO2). If the trigger input (slave mode controller in reset mode) produces a reset, the signal on TRGO is relative to the actual reset. There will be a delay.</p> <p>0001: Enable-Counter enable signal CNT_EN may be used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the counter enable signal is controlled by the trigger input, there is a delay on the TRGO unless the master/slave mode is selected (see description of the MSM bit in the TIMx_SMCR register).</p> <p>0010: UPDATE-The update event is selected as the trigger output (TRGO2). For instance a master timer can then be used as a prescaler for a slave timer.</p> <p>0011: Comparison Pulse-Once a catch occurs or a comparison is successful, when the CC1IF flag is to be set (i.e. it is already high), the trigger output sends a positive pulse (TRGO2).</p> <p>0100: Compare-OC1REFC signal is used as trigger output (TRGO2).</p> <p>0101: Compare-OC2REFC signal is used as trigger output (TRGO2).</p> <p>0110: Compare-OC3REFC signal is used as trigger output (TRGO2).</p> <p>0111: Compare-OC4REFC signal is used as trigger output (TRGO2).</p> <p>1000: Compare-OC5REFC signal is used as trigger output (TRGO2).</p> <p>1001: Compare-OC6REFC signal is used as trigger output (TRGO2).</p> <p>1010: Comparison pulse-OC4REFC signal rising or falling edge is used as trigger output (TRGO2).</p> <p>1011: Comparison pulse-rising or falling edge of OC6REFC signal is used as trigger output (TRGO2).</p> <p>1100: Comparison pulse-OC4REFC signal rising edge or OC6REFC signal rising edge used as trigger output (TRGO2).</p> <p>1101: Comparison pulse-OC4REFC signal rising edge or OC6REFC signal falling edge is used as trigger output (TRGO2).</p> <p>1110: Comparison pulse-OC5REFC signal rising edge or OC6REFC signal rising edge is used as trigger output (TRGO2).</p> <p>1111: Comparison pulse-OC5REFC signal rising edge or OC6REFC signal falling edge is used as trigger output (TRGO2).</p> <p>NOTE: The clock of the slave timer or ADC must be turned on before receiving the master timer event and not changed while receiving it.</p> |

|   |          |    |   | <p>0000: Reset-The UG bit of the TIMx_EGR register is used as a trigger output (TRGO). If the reset is generated by the trigger input (the slave mode controller is in reset mode), the signal on the TRGO will have a delay relative to the actual reset.</p> <p>0001: Enable-Counter enable signal CNT_EN may be used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the counter enable signal is controlled by the trigger input, there is a delay on the TRGO unless the master/slave mode is selected (see description of the MSM bit in the TIMx_SMCR register).</p> <p>0010: Update-The update event is selected as Trigger Output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.</p> <p>0011: Comparison Pulse-When a catch occurs or a comparison is successful, when the CC1IF flag is to be set (even if it is already high), the trigger output sends a positive pulse (TRGO).</p> <p>0100: Compare - OC1REFC signal is used as trigger output (TRGO)</p> <p>0101: Compare - OC2REFC signal is used as trigger output (TRGO)</p> <p>0110: Compare - OC3REFC signal is used as trigger output (TRGO)</p> <p>0111: Compare - OC4REFC signal is used as trigger output (TRGO)</p> <p>1000: Encoder clock output-encoder clock signal as trigger output (TRGO). This encoded value is only valid if the SMS [3: 0] has values of 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Other SMS values may result in unexpected effects.</p> <p>1001-1111: Reserved</p> <p>Note:</p> <ol style="list-style-type: none"> <li>1. The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed.</li> <li>2. If the master and slave timers are not on the same bus, the master mode should be configured to the width that can be picked by the slave timer.</li> </ol> |

| 2: 0 | SMS  | RW | 3'h0 | <p>Select from Mode (Slave mode selection)<br/> When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).<br/> 0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.<br/> 0001: Quadrature Encoder Mode 1, x2 Mode-The counter counts up/down on the edge of TI1FP1 depending on the level of TI2FP2.<br/> 0010: Quadrature Encoder Mode 2, x2 Mode-The counter counts up/down on the edge of TI2FP2 depending on the level of TI1FP1.<br/> 0011: Quadrature Encoder Mode 3, x4 Mode-The counter counts up/down on the edges of TI1FP1 and TI2FP2 depending on the input level of the other signal.<br/> 0100: Reset Mode-The rising edge of the selected trigger input (TRGI) reinitializes the counter and generates a signal to update the register.<br/> 0101: Gated mode-When the trigger input (TRGI) is high, the clock of the counter is turned on. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.<br/> 0110: Trigger mode-The counter starts (but does not reset) on the rising edge of the trigger input TRGI, only the start of the counter is controlled.<br/> 0111: External clock mode 1-The rising edge of the selected trigger input (TRGI) drives the counter.<br/> 1000: Reset + Trigger Combination Mode:-Rising edge of Trigger Input (TRGI) initializes counter, generates register update and starts counter<br/> 1001: Gate + Reset Combination Mode:-Trigger input (TRGI) is high when counter clock enabled. The counter stops and resets once the trigger signal is pulled low. The start and stop of the counter are controllable.<br/> 1010: Encoder mode: clock + direction, x2 mode<br/> 1011: Encoder mode: clock + direction, x1 mode, sensitivity of TI2FP2 set by CC2P<br/> 1100: encoder mode: directional clock, x2 mode<br/> 1101: Encoder mode: directional clock, x1 mode, sensitivity of TI1FP1, TI2FP2 set by CC1P and CC2P<br/> 1110: quadrature encoder mode: x1 mode. Count only at the edge of TI1FP1, the edge sensitivity is set by CC1P<br/> 1111: quadrature encoder mode: x1 mode. Counted only at the edge of TI2FP2, the edge sensitivity is set by CC2P<br/> Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.<br/> Note: The slave device (timer, ADC) must be enabled to receive TRGO or TRGO2 before receiving the master timer event, and the clock frequency can no longer be changed during reception<br/> Note: Do not use UEV as the tim_trgo output signal in encoder mode (i.e. mms cannot be configured to 010)</p> |

Especially when the dead band is active, the output is always output according to the rules of the dead band output, although at this time moe may have been set to 1 by software or hardware. If neither of the two outputs of a channel is used (CCxE = CCxNE = 0), then OISx, OISxN, CCxP, and CCxNP must all be cleared.

|      |          |    |   | <p>whereas OC5 and OC5N active level depends on CC5P and CC5NP bits.</p> <p>0000: Frozen. The comparison between the output comparison register TIMx_CCR5 and the counter TIMx_CNT has no effect on OC5REF;</p> <p>0001: Set channel 1 to active level on match. When the value of counter TIMx_CNT is the same as that of capture/compare register 1 (TIMx_CCR5), OC5REF is forced to be high.</p> <p>0010: Set channel 1 to inactive level on match. OC5REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR5).</p> <p>0011: Toggle OC5REF toggles when TIMx_CNT=TIMx_CCR5.</p> <p>0100: Force inactive level OC5REF is forced low.</p> <p>0101: Force active level OC5REF is forced high.</p> <p>0110: PWM Mode 1-On up count, channel 5 is active once TIMx_CNT &lt; TIMx_CCR5, otherwise it is invalid; On counting down, channel 5 is an inactive level (OC5REF = 0) once TIMx_CNT &gt; TIMx_CCR5, otherwise it is an active level (OC5REF = 1).</p> <p>0111: PWM mode 2 - In upcounting, channel 5 is inactive as long as TIMx_CNT&lt;TIMx_CCR5 else active. In downcounting, channel 5 is active as long as TIMx_CNT&gt;TIMx_CCR5 else inactive.</p> <p>1000: Retriggerable OPM Mode 1-In incremental count mode, the channel is active until a trigger event (TRGI signal) is detected. Then, the comparison is performed as in PWM mode 1, and the channel becomes valid again at the next update. In decrement count mode, the channel is invalid until a trigger event (TRGI signal) is detected. Then, the comparison is performed as in PWM Mode 1, and the channel becomes inactive again at the next update</p> <p>1001: Retriggerable OPM Mode 2-In incremental count mode, the channel is in an invalid state until a trigger event (TRGI signal) is detected. Then, the comparison is performed as in PWM mode 2, and the channel becomes invalid again at the next update. In decrement count mode, the channel is active until a trigger event (TRGI signal) is detected. Then, the comparison is performed as in PWM Mode 2, and the channel becomes active again at the next update</p> <p>Others: Reserved</p> <p>Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).</p> <p>Note 2: In PWM mode, the OC5REF level is changed only when the comparison result is changed or when the output comparison mode is switched from freeze mode to PWM mode.</p> <p>Note 3: This bit segment can be preloaded when the channel has complementary outputs. If the CCPC position of TIMx_CR2 is 1, then the OC5M valid bit is updated with a new value from the preload only when the COM event is generated</p> <p>Note 4: When using repeatable OPM mode, do not configure the counting mode as central counting mode</p> |

## 20. General Purpose Timer (TIM2 to TIM5 / TIM18)

### 20.1 Introduction

The Universal Control Timer (TIMx) consists of a 32-bit or 16-bit auto-load counter driven by a programmable prescaler. It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion). Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers. The Universal Control Timer (TIMx) and the Advanced Timer (TIMx) are completely independent, they do not share any resources. They can be synchronized together.

#### 20.1.1 TIM2/3/4/5/18 Main Features

Key features include:

- 32-bit (TIM2) or 16-bit (TIM3/4/5/18) up, down, up/down auto-load counter
- 16-bit programmable (can be modified in real time) prescaler, the frequency division coefficient of the counter clock frequency is any value between 1 and 65536
- Up to 4 independent channels:
  - Input capture
  - Output compare
  - PWM generation (edge or center alignment mode)
  - One-pulse mode output
- Synchronization circuit for controlling timer and interconnection between timer by external signal
- An interrupt/DMA occurs when the following events occur:
  - Update: Counter upflow/downflow, counter initialization (via software or internal/external trigger)
  - Trigger event (counter starts, stops, initializes or counts by internal/external triggers)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoders for positioning
- Trigger input for external clock or cycle-by-cycle current management

## 20.1.2 CAN block diagram

## 20.2 TIM2/3/4/5/18 Functional Description

### 20.2.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The clock of the counter may be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time base unit comprises:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Autoload Register (TIMx\_ARR)

An autoloader register is preloaded, and a write or read autoloader register will access its preload register. The contents of the preload register are transferred to the shadow register either immediately or at each update event (UEV), depending on the setting of the Autoload preload enable bit (ARPE) in the TIMx\_CR1 register. An update event occurs when the counter reaches an overflow condition (overflow or underflow) and when the UDIS bit in the TIMx\_CR1 register is equal to 0. The update event may also be generated by software and other conditions. The generation of update events under each configuration will be described in detail later.

The counter is driven by the clock output CK\_CNT divided by the prescaler, which is valid for the counter only when the counter enable bit (CEN) in the TIMx\_CR1 register is set. (See the description of the slave mode controller for more details on enabling counters).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR register.

### Prescaler description

The prescaler can divide the clock frequency of the counter by any value between 1 and 65536. It is a 16-bit counter controlled based on a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescalation parameters will be adopted when the next update event comes.

The following figures give examples of changing counter parameters when the prescaler is running.

Figure 20-1 Timing diagram of the counter when the parameters of the prescaler change from 1 to 2

Figure 20-2 Timing diagram of the counter when the parameter of the prescaler is changed from 1 to 3

## 20.2.2 Counter mode

### Upcounting mode

In the count-up mode, the counter counts from 0 to the auto-load value (the content of TIMx\_ARR), then counts from 0 again and generates a count overflow event. Setting the UG bit in the TIMx\_EGR register (either by software or using a slave mode controller) can also generate an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. No update event will be generated until the UDIS bit is cleared '0'. Even so, when an update event should occur, the counter is still cleared '0', and the counter inside the prescaler is also cleared '0' (but the value of the prescaler remains unchanged).

Furthermore, if the URS bit in the TIMx\_CR1 register is set (select the update request source), an update event UEV can be generated by setting the UG bit, but the UIF flag bit will not be set (i.e., no interrupt or DMA request will be generated). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all of the following registers are updated, and the hardware sets an update flag bit (UIF bit in the TIMx\_SR register) at the same time (according to the URS bit):

- The auto-load shadow register is updated with the preload value (TIMx\_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 20-3 Counter timing diagram, internal clock divided by 1

Figure 20-4 Counter timing diagram, internal clock divided by 2

Figure 20-5 Counter timing diagram, internal clock divided by 4

Figure 20-6 Counter timing diagram, internal clock divided by N

Figure 20-7 Counter timing diagram, update event when ARPE=0 (no TIMx\_ARR preloaded)

Figure 20-8 Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)

### Downcounting mode

In down-count mode, the counter starts from the auto-loaded value (the contents of TIMx\_ARR) and counts down to 0, then restarts from the auto-loaded value and generates a count underflow event. Setting the UG bit in the TIMx\_EGR register (either by software or using a slave mode controller) can also generate an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. Even then, when an update event should occur, the counter will restart counting from the current autoloading value while the counter inside the prescaler is cleared '0' (but the prescaling factor remains unchanged).

In addition, if the URS bit in the TIMx\_CR1 register is set (select the update request source), an update event UEV can be generated by setting the UG bit, but the UIF flag bit is not set (i.e., no interrupt or

DMA request will be generated), in order to avoid clearing the counter when a capture event occurs, and generating both an update and a capture interrupt.

When an update event occurs, all of the following registers are updated, and the hardware sets an update flag bit (UIF bit in the TIMx\_SR register) at the same time (according to the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register).

Note: The autoloading value is updated before the counter is reloaded, so the next cycle will be the expected value.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 20-9 Counter timing diagram, internal clock divided by 1

Figure 20-10 Counter timing diagram, internal clock divided by 2

Figure 20-11 Counter timing diagram, internal clock divided by 4

Figure 20-12 Counter timing diagram, internal clock divided by N

Figure 20-13 Counter timing diagram, update event when repetition counter is not used

### Central alignment mode (up/down count)

In central alignment mode, the counter starts counting from 0 to the auto-loaded value (TIMx\_ARR register) minus 1, generating a counter overflow event, and then counts down to 1 and generating a counter underflow event; Then re-count from 0 again.

The center alignment mode can be obtained by configuring the CMS bit in the TIMx\_CR1 register not to be '00'. The output comparison flag bit with the channel configured as output mode is set during the following counting processes: when counting down (center alignment mode 1, CMS = '01'), when counting up (center alignment mode 2, CMS = '10'), and when counting up and down (center alignment mode 3, CMS = '11').

In this mode, the DIR direction bit in the TIMx\_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. The counter then starts counting again from 0, and the prescaler internal counter also starts counting again from 0.

Setting the UDIS bit in the TIMx\_CR1 register can disable the update event. This is to avoid updating the shadow registers while writing new values in the preload registers. Although no update event will occur until the UDIS bit is cleared to 0, the counter will continue to count up or down based on the value of the current auto-reload.

Furthermore, if the URS bit in the TIMx\_CR1 register is set (select the update request source), by setting the UG bit, an update event UEV will be generated but the UIF flag will not be set (thus no interrupts and DMA requests are generated), in order to avoid clearing the counter when a capture event occurs, while generating both an update and a capture interrupt.

When an update event occurs, all registers are updated and (according to the setting of the URS bit) an update flag bit (UIF bit in the TIMx\_SR register) is also set:

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note: If an update occurs due to a counter overflow, the automatic reload will be updated before the counter is reloaded, so the next cycle will be the expected value (the counter is loaded as a new value).

Here are some examples of how the counter operates at different clock frequencies:

### 20.2.3 External trigger input

The timer external trigger input `tim_etr` can be used to:

- External clock
- From the trigger of the pattern
- As a PWM reset input in periodic current regulation

### 20.2.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode 1: External input pins (TI1 and TI2)
- External clock mode2: external trigger input ETR
- Internal Trigger Input (ITRx): Uses one timer as a prescaler for the other. For example, one timer Timer1 may be configured as a prescaler for another timer Timer2.

## Encoder Mode

### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS = 0000), the CEN, DIR (TIMx\_CR1 register), and UG bits (TIMx\_EGR register) are de facto control bits and can only be modified by software (the UG bits are still automatically cleared). As long as the CEN bit is written as '1', the clock of the prescaler is provided by the internal clock CK\_INT.

The diagram below shows the operation of the control circuit and up counter in general mode, without the prescaler.

Figure 20-20 Control circuit in normal mode, internal clock divided by 1

### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 20-21 TI2 Example of external clock connection

For example, to configure the counter to count up on the rising edge of the TI2 input, use the following steps:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure IC2F [3: 0] of the TIMx\_CCMR1 register and select the input filter bandwidth (if no filter is needed, keep IC2F = 0000);

3. Select rising edge polarity by writing CC2P=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=00110 in the TIMx\_SMCR register;
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge of TI2 and the actual clock of the counter depends on the synchronization circuit at the input of TI2.

Figure 20-22 Control circuit in external clock mode 1

### External clock source mode 2

This mode is selected by making ECE = 1 in the TIMx\_SMCR register, and the counter can externally trigger each rising or falling edge of the ETR to count.

The following figure is a block diagram of the external trigger input:

Figure 20-23 External trigger input block diagram

For example, to configure an up-counter that counts every 2 rising edges under ETR, use the following steps:

1. No filter is needed in this example, set ETF [3: 0] = 0000 in the TIMx\_SMCR register;
2. Set the prescaler and set ETPS [1: 0] = 01 in the TIMx\_SMCR register;
3. Select the rising edge of the ETR input terminal and set ETP = 0 in the TIMx\_SMCR register;
4. Turn on external clock mode 2 and write ECE = 1 in the TIMx\_SMCR register;
5. Start counter, write CEN = 1 in TIMx\_CR1 register;

The counter counts at every 2 ETR rising edges.

The delay between the rising edge of the ETR and the actual clock of the counter depends on the synchronization circuit of the ETRP signal.

Figure 20-24 Control circuit in external clock mode 2

### 20.2.5 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figures are capture/compare channel overviews.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. An edge monitor with polarity selection then generates a signal (TIxFPx) that can be triggered as an input from the slave mode controller or as a capture control. It is prescaled before the capture register (ICxPS).

Figure 20-25 Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 20-26 Capture/Compare the main circuit of channel 1

Figure 20-27 Output stage of capture/compare channel (channel 1 to 4)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 20.2.6 Input capture mode:

In input capture mode, when the corresponding edge on the ICx signal is detected, the current value of the counter is latched into the capture/compare register (TIMx\_CCRx). When a capture event occurs, the corresponding CCxIF flag (TIMx\_SR register) is set to 1, and if an interrupt or DMA operation is enabled, an interrupt or DMA request will be generated. If the CCxIF flag is already high when the capture event occurs, the over-capture flag CCxOF (TIMx\_SR register) is set to 1. The CCxIF can be cleared by writing CCxIF = 0, or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1input rises. To do this, use the following procedure:

- Select valid input: TIMx\_CCMR1 must be connected to the TI1 input, so CC1S = 01 written in the TIMx\_CCMR1 register, as long as CC1S is not '00', the channel is configured as input, and the TIMx\_CCR1 register becomes read-only.
- Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register)). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the valid transition edge of the TI1 channel and write CC1P = 0 (set to rising edge) in the TIMx\_CCER register.
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If desired, the associated interrupt request may be allowed by setting the CC1IE bit in the TIMx\_DIER register, or the DMA request may be allowed by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- The CC1IF flag bit is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 20.2.7 PWM input mode

This mode is a special case of the input capture mode, and the rest of the operation is the same as the input capture mode except for the following differences:

- Both ICx signals are mapped to the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the cycle (TIMx\_CCR1 register) and the duty cycle (TIMx\_CCR2 register) of the PWM signal input to TI1 as follows

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P bit to '0' (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2Pbit to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

Figure 20-28 PWM input mode timing

Because only TI1FP1 and TI2FP2 are connected to the slave mode controller, the PWM input mode can only use the TIMx\_CH1/TIMx\_CH2 signal.

### 20.2.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compares signal(OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

Set the corresponding OCxM = 0101 in the TIMx\_CCMRx register to force the output comparison signal (OCxREF/OCx) to an active state. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx\_CCMRx register. Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 20.2.9 Output compare mode

This function is used to control an output waveform or indicate that a given period of time has expired. When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).
- If the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register selects the DMA request function), a DMA request is generated.

You can select whether the TIMx\_CCRx register needs to use a preload register by configuring the OCxPE bit in TIMx\_CCMRx.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxEN = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated by software at any time to control the output waveform, provided the preload register is not used (OCxPE = '0', otherwise the shadow register of TIMx\_CCRx can only be updated when the next update event occurs). An example is given in the figure below.

Figure 20-29 Output comparison mode, flip OC1

### 20.2.10 PWM mode

The pulse width modulation mode may produce a signal whose frequency is determined by the TIMx\_ARR register and whose duty cycle is determined by the TIMx\_CCRx register.

The OCxM bit in the TIMx\_CCMRx register is written to '0110' (PWM mode 1) or '0111' (PWM mode 2), and each OCx output channel can be independently set to generate a PWM. The corresponding preload register must be enabled by setting the OCxPE bit of the TIMx\_CCMRx register, and finally the ARPE bit of the TIMx\_CR1 register to enable the preload register that is automatically reloaded (in up-count or centrosymmetric mode).

The preload register can only be transferred to the shadow register when an update event occurs, so the user must initialize all registers by setting the UG bit in the TIMx\_EGR register before the counter starts counting.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. The output of OCx is enabled to be controlled by (TIMx\_CCER) CCxE, CCxNE. Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

#### PWM edge-aligned mode

##### ■ Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the comparison value in TIMx\_CCRx is greater than the auto-reload value (TIMx\_ARR), OCxREF remains '1'. If the comparison value is 0, then OCxREF remains '0'. Figure below shows some edge-aligned PWM waveforms in an example where  $TIMx\_ARR=8$ .

Figure 20-30 Edge-aligned PWM waveforms (ARR=8)

#### ■ Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high.

In PWM mode 1, the reference signal OCxRef is low as long as  $TIMx\_CNT > TIMx\_CCRx$  else it becomes high. If the comparison value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, OCxREF remains '1'. 0% PWM is not possible in this mode.

#### PWM Central Alignment Mode

The center alignment mode is when the CMS bit in the TIMx\_CR1 register is not '00' (all other configurations of the CMS bit have the same effect on the OCxREF/OCx signal). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software.

The following figure gives some examples of centrally aligned PWM waveforms

- TIMx\_ARR = 8
- PWM mode is the PWM mode 1
- CMS = 01 for the TIMx\_CR1 register, in center alignment mode 1, the compare flag is set when the counter counts down.

Figure 20-31 Centre-aligned PWM waveform (APR = 8)

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx\_CR1 register. Also, do not modify the DIR and CMS bits simultaneously through software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:

-If the value of the write counter is greater than the value of the auto-reload (TIMx\_CNT > TIMx\_ARR), the direction is not updated.

For example, if the counter was counting up, it continues to count up.

-If a value of 0 or TIMx\_ARR is written to the counter, the direction is updated, but no update event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### Jitter mode

The DITHEN bit of the TIMx\_CR1 register may be enabled to turn on the jitter mode to improve the effective resolution of the PWM mode. Can be applied to CCR (improved duty cycle resolution) and ARR (improved resolution of PWM frequency)

The principle of operation is to make the actual CCR (or ARR) value change slightly (with or without increasing a timer cycle) over 16 consecutive PWM cycles, and how the change can be set by predefined settings. When calculating the average duty cycle, you can achieve a 16-fold increase in resolution. The figure below shows the jitter principle of four consecutive PWM periods

Figure 20-32 jitter principle

When jitter mode is enabled, the value of the register will automatically change as follows:

- The lowest 4 bits is the encoding for improving resolution (fractional part)
- The high bit is shifted left to 19: 4 for encoding as the base value (integer part)

Note: When dither mode is on or off, the values of ARR and CCR are automatically updated (for example, ARR = 0x05 when DITHEN = 0, then ARR = 0x50 when DITHEN = 1), the following steps must be followed when resetting the DITHEN bit

1. CEN and ARPE bits must be reset
2. The ARR [3: 0] bit must be reset
3. The DITHEN bit must be reset
4. The CCIF flag must be cleared
5. CEN bit can be set (ARPE = 1 can be set)

Figure 20-33 Data mapping and register coding in dither mode

The minimum frequency is calculated as follows:

$$\text{According to resolution} = \frac{\text{定时器频率}}{\text{PWM 频率}} \quad \text{push out: minimum PWM frequency} = \frac{\text{定时器频率}}{\text{最大分辨率}}$$

In jitter-free mode: Minimum PWM frequency =  $\frac{\text{定时器频率}}{65536}$

When there is jitter mode: minimum PWM frequency =  $\frac{\text{定时器频率}}{65535 + \frac{15}{16}}$

Note: The maximum values of TIMx\_arr and TIMxCCRy in jitter mode are limited to 0xFFFFEF (corresponding to 65534 in the integer part and 15 in the jitter part). Exceeding 0xFFFFEF, there will be an overflow situation, that is, arr = 0xFFFF+1 = 0.

The figure below shows that in jitter mode, the resolution of the PWM can be improved regardless of the PWM frequency

Figure 20-34 PWM resolution vs frequency

The duty cycle and cycle changes in 16 consecutive cycles are as follows:

Figure 20-35 PWM Jitter Mode

The auto-reload and compare value increments are distributed in a specific pattern as described in the table below, with the incremental distribution of the jitter sequence as uniformly as possible, minimizing overall ripple.

Table 20-1 CCR and ARR Register Jitter Changes

| LSB value | PWM Cycle |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|           | 1         | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| 0000      |           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0001      | +1        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0010      | +1        |    |    |    |    |    |    |    | +1 |    |    |    |    |    |    |    |
| 0011      | +1        |    |    |    | +1 |    |    |    | +1 |    |    |    |    |    |    |    |
| 0100      | +1        |    |    |    | +1 |    |    |    | +1 |    |    |    | +1 |    |    |    |
| 0101      | +1        |    | +1 |    | +1 |    |    |    | +1 |    |    |    | +1 |    |    |    |
| 0110      | +1        |    | +1 |    | +1 |    |    |    | +1 |    | +1 |    | +1 |    |    |    |
| 0111      | +1        |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |    |    |
| 1000      | +1        |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |
| 1001      | +1        | +1 | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    | +1 |    |
| 1010      | +1        | +1 | +1 |    | +1 |    | +1 |    | +1 | +1 | +1 |    | +1 |    | +1 |    |
| 1011      | +1        | +1 | +1 |    | +1 | +1 | +1 |    | +1 | +1 | +1 |    | +1 |    | +1 |    |
| 1100      | +1        | +1 | +1 |    | +1 | +1 | +1 |    | +1 | +1 | +1 |    | +1 | +1 | +1 |    |
| 1101      | +1        | +1 | +1 | +1 | +1 | +1 | +1 |    | +1 | +1 | +1 |    | +1 | +1 | +1 |    |
| 1110      | +1        | +1 | +1 | +1 | +1 | +1 | +1 |    | +1 | +1 | +1 | +1 | +1 | +1 | +1 |    |
| 1111      | +1        | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 | +1 |    |

The dither mode can also be applied in the intermediate alignment PWM mode (CMS! = 00). The figure below considers the case where the dither mode is applied to 8 consecutive cycles when counting up and down.

Figure 20-36 Effect of jitter on duty cycle in aligned PWM mode in middle of the figure

Table 20-2 Change of CCR Register Jitter in Middle Aligned PWM Mode

| LSB value | PWM Cycle |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|           | 1         |    | 2  |    | 3  |    | 4  |    | 5  |    | 6  |    | 7  |    | 8  |    |

### 20.2.11 Asymmetric PWM mode

The asymmetric mode allows two centrally aligned PWM signals to produce a programmable phase shift. When the frequency is determined by TIMx\_ARR and the duty cycle and phase shift are determined by a pair of TIMx\_CCRx registers. The asymmetric mode allows the generation of two center-aligned PWM signals using programmable phase shifts. One TIMx\_CCRx register is controlled during the up-count phase and the other during the down-count phase so that the PWM can be adjusted every half PWM cycle

- The OC1REFC(orOC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- The OC3REFC(orOC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

By writing 1110 to OCxM (asymmetric PWM mode 1) and 1111 to OCxM (asymmetric PWM mode 2), asymmetric PWM mode can be independently selected on dual channels (each pair of CCR registers controls one OCx output)

Note: For compatibility reasons, the OCxM [3: 0] field is divided into two parts, with the highest and lower 3 bits not contiguous.

When a given channel is used as an asymmetric channel, its adjacent channels (channel 1 adjacent to channel 2) can also be used. For example, if OC1REFC is generated by channel 1 (asymmetric PWM mode 1), channel 2 may also output OC2REF, or OC2REFC through asymmetric PWM mode 1. The figure below represents an example of using asymmetric PWM mode to generate signals (channels 1 through 4 are configured as asymmetric PWM mode 2), which, together with the dead time generator, controls a full-bridge DC-DC phase shift inverter.

Figure 20-37 2 50% duty cycle phase shift PWM

### 20.2.12 Combined PWM mode

The combined PWM mode allows an edge or center aligned PWM signal to be generated by programmable delay and phase shift between pulses. The frequency is determined by the ARR and the duty cycle and delay are determined by the two CCRs. The resulting signal OCxREFC is generated by AND/OR logic between two reference PWMs

- The OC1REFC(orOC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- The OC3REFC(orOC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM modes can be independently selected on dual channels (each pair of CCR registers controls one OCx output) by writing to OCxM 1100 (combined PWM mode 1, logic OR output) and OCxM 1101 (combined PWM mode 2, logic AND output)

When a given channel is used as a combined PWM channel, its complementary channels must be configured in opposite PWM modes (e.g., one for combined PWM mode 1 and one for combined PWM mode 2).

The following figure shows an example of a combined mode generation signal, including

- Channel 1 is combined PWM mode 2
- Channel 2 is PWM Mode 1
- Channel 3 is combined PWM mode 2
- Channel 4 is PWM Mode 1

Figure 20-38 Combined PWM patterns for channel 1 and channel 3

### 20.2.13 Clearing the OCxREF signal on an external event

For a given channel, setting the corresponding OCxCE bit in the TIMx\_CCMRx register to '1' enables the OCxREF signal to be pulled low with a high level at the OCREF\_CLR\_INT input, and the OCxREF

signal will remain low until the update event UEV generated by the next count overflow occurs. This function can only be used in output compare and PWM modes. It does not work in Forced mode. While OCREF\_CLR\_INT can be selected between OCREF\_CLR and ETRF (after ETR filtering) by configuring the OCCS bit in the TIMx\_SMCR register.

Figure 20-39 OCREF\_CLR input selection

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx\_SMCR register set to '0'.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured as needed.

The figure below shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is placed in PWM1 mode.

Figure 20-40 OCxREF for clearing TIMx

### 20.2.14 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV. A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- Up count mode: counter  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),
- Down counting mode: Counter  $CNT > CCRx$ .

Figure 20-41 Example of one pulse mode

For example one may want to generate a positive pulse on OC1 with a length of  $tPULSE$  and after a delay of  $tDELAY$  as soon as a positive edge is detected on the TI2 input pin.

Assume TI2FP2 as the trigger:

- Map TI2FP2 on TI2 by writing  $CC2S=01$  in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write  $CC2P=0$  in the TIMx\_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing  $TS=110$  in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing  $SMS$  to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $tDELAY$  is defined by the value written in the TIMx\_CCR1 register.
- The  $tPULSE$  is defined by the difference between the auto-reload value and the compare value ( $TIMx\_ARR - TIMx\_CCR1$ ).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '0' to '1' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing  $OC1M=111$  in the TIMx\_CCMR1 register. Optionally the preload registers can be enabled by writing  $OC1PE='1'$  in the TIMx\_CCMR1 register

and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example. In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0) When OPM bit in the TIMx\_CR1 register is set to '0', so the repetitive mode is selected.

#### 20.2.14.1 Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations, and it limits the minimum delay tDELAY min we can get. If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx\_CCMRx register. Then OCxREF (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

#### 20.2.15 Retriggerable Single Pulse Mode

This mode allows the counter to start in response to excitation and generate pulses of programmable length, which differs from the non-retriggerable single pulse mode described in the previous section as follows:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- If a new trigger occurs before the pulse generated by the previous trigger is completed, the pulse is extended.

To use the retriggerable monopulse mode, the timer must be in slave mode, the bit SMS [3: 0] = "1000" in the TIMx\_SMCR register (combined mode-reset + trigger), and the OCxM [3: 0] bit set to "1000" or "1001" (retriggerable OPM mode 1 or 2).

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: For compatibility reasons, the OCxM [3: 0] and SMS [3: 0] bit fields are split into two parts, with the most significant bit not contiguous with the 3 least significant bit positions.

This mode must not be used in conjunction with the central alignment count mode. CMS [1: 0] = 00 must be in TIMx\_CR1.

Figure 20-42 Example of a retriggerable monopulse mode

### 20.2.16 Comparison mode generation pulse

Pulses may be generated by comparing matching events. When the counter value is equal to the given comparison value, a programmable width pulse signal is generated for debugging and synchronization purposes.

This mode can be used with any slave mode, including encoder mode. It is only available for 3/4 channels in edge and center alignment counting mode. The pulse generator is unique and shared by these two channels, as shown in the following figure:

Figure 20-43 Pulse generator circuit

The following figure shows how pulses are generated in edge counting and encoder modes:

Figure 20-44 Generate pulses by comparing events in edge alignment and center alignment modes

The output comparison mode is selected by OC3M [3: 0] and OC4M [3: 0] in TIMx\_CCMR2

The pulse width is programmed via the PW [7: 0] register, using the clock generated by clock prescaling via PWPRSC [2: 0]

$$t_{PW} = PW[7:0] \times t_{PWG}$$

$$t_{PWG} = xCK \cdot 2^{(PWPRSC[2:0])} \cdot \text{INT}$$

The resolution and maximum value depend on the value of the prescaler

Pulse re-trigger: When the pulse is output normally, a new trigger comes, which will cause the pulse to be extended

Note: If both channels are enabled at the same time, the pulses output are independent as long as the trigger on one channel does not overlap with the pulses generated by the other channel. If the two triggers overlap, the trigger 1 generation pulse will be extended (will be re-triggered), and the last trigger generation pulse width will be correct.

Figure 20-45 Generate pulses by comparing events in edge alignment and center alignment modes

## 20.2.17 Encoder interface mode

### 20.2.17.1 Quadrature encoder

To select Encoder Interface mode: write SMS='0001' in the TIMx\_SMCR register if the counter is counting on TI1 edges only, SMS=0010 if it is counting on TI2 edges only and SMS=0011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, you can program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Referring to the table below, assuming that the counter has been started (CEN = 1 in the TIMx\_CR1 register), the counter is driven by each valid jump on TI1FP1 or TI2FP2. TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx\_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together. In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 20-3 Relationship between counting direction and encoder signal (CC1P = CC2P = 0)

| Effective edge                                        | SMS [3: 0] | Reverse signal level<br>(TI1FP1 for TI2,<br>TI2FP2 for TI1) | TI1FP1 signal |         | TI2FP2 signal |         |
|-------------------------------------------------------|------------|-------------------------------------------------------------|---------------|---------|---------------|---------|
|                                                       |            |                                                             | Rising        | Falling | Rising        | Falling |
| Count only at TI1<br>single edge<br>x1 mode           | 1110       | High                                                        | Minus         | Add     | -             | -       |
|                                                       |            | Low                                                         | -             | -       | -             | -       |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The figure below gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = '01' (TIMx\_CCMR1 register, TI1FP1 mapped to IC1)
- CC2S = '01' (TIMx\_CCMR2 register, TI2FP2 mapped to IC2)
- CC1P = '0' (TIMx\_CCER register, TI1FP1 is not inverted, TI1FP1 = TI1)
- CC2P = '0' (TIMx\_CCER register, TI2FP2 is not inverted, TI2FP2 = TI2)
- SMS = '011' (TIMx\_SMCR register, all inputs are valid on rising and falling edges).
- CEN = '1' (TIMx\_CR1 register, counter enabled)

Figure 20-46 Example of counter operation in encoder interface mode

The following figure shows an operation example of the counter when the polarity of IC1FP1 is inverted (CC1P = '1', other configurations are the same as the above example)

Figure 20-47 IC1FP1 Inverted Encoder Interface Mode Example

The figure below shows the count value when the steering turns over in different modes:

Figure 20-48 Quadrature Encoder Counting Mode

When the timer is configured in the encoder interface mode, information of the current position of the sensor may be provided. By configuring the second timer in the capture mode, the interval between the two encoder events can be measured, and dynamic information (speed, acceleration, deceleration) can be obtained. An encoder output indicating a mechanical zero may be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. If possible, you can latch the value of the counter to the third input capture register (the capture signal must be periodic and can be generated by another timer); Its value can also be read by a DMA request generated by a real-time clock.

The UIFREMAP bit of the TIMxCR1 register forces the continuous copy of the update interrupt flag (UIF) to the highest bit of the timer counter (TIMxCNT [31]). This allows the count value and a state generated by the UIFCPY flag to be readable. This simplifies the calculation of angular velocity by avoiding causing race conditions. For example, by sharing processing between background tasks (counter readout) and interrupts (interrupt updates

There is no delay between UIF and UIFCPY flag assertions

In a 32-bit counter design, when the UIFREMAP bit is set, the 31st bit of the counter is overwritten by the UIFCPY flag when reading (the most significant bit of the counter is only accessible in write mode)

### 20.2.17.2 Clock plus directional encoder mode

In addition to quadrature encoders, the timer also supports other different types of encoder modes

Clock plus direction mode As shown in the figure, the clock is provided by TI2 and the direction is input by TI1, this mode is enabled by configuring the SMS [3: 0] of the TIMx\_SMCR register as follows:

- 1010: x2 mode, counter updates on rising and falling edges of clock
- 1011: x1 mode, counter is updated at one edge, rising edge is updated at CC2P = 0, falling edge is updated at CC2P = 1

The polarity of the directional signal input to TI1 is determined by the CC1P bit, CC1P = 0: positive polarity (count up when TI1 is high, count down when TI1 is low); CC1P = 1: negative polarity (count down when TI1 is high, count up when TI1 is low)

Figure 20-49 direction plus clock encoder mode

### 20.2.17.3 Directional clock encoder mode

In directional clock mode (shown in the figure below), the clock is provided by two signals, one at a time depending on the direction, thus having an up-count clock signal (TI2) and a down-count clock signal (TI1). This mode is enabled by configuring the SMS [3: 0] of the TIMx\_SMCR register as follows:

- 1100: x2 mode, regardless of which clock line, the counter is updated on both the rising and falling edges of the clock. The clock initial state may be configured by the CC1P and CC2P bits. CCxP = 0 represents a high level initial state and CCxP = 1 represents a low level initial state
- 1101: x1 mode, the counter is updated at one edge, depending on the values of CCx1P and CCx2P. CCxP = 0 indicates a falling edge count and the initial state is high. CCxP = 1 indicates a rising edge count and the initial state is low.

Figure 20-50 Directional Clock Encoder Mode (CC1P = CC2P = 0)

Figure 20-51 Directional Clock Encoder Mode (CC1P = CC2P = 1)

The following table details how the directional clock mode operates for any input transition:

Table 20- 4 Relationship between counting direction and encoder signal polarity

| Effective edge      | SMS [3: 0] | Reverse signal level<br>(TI1FP1 for TI2,<br>TI2FP2 for TI1) | TI1FP1 signal |         | TI2FP2 signal |         |
|---------------------|------------|-------------------------------------------------------------|---------------|---------|---------------|---------|
|                     |            |                                                             | Rising        | Falling | Rising        | Falling |
| x2 mode<br>CCxP = 0 | 1100       | High                                                        | Minus         | Minus   | Add           | Add     |
|                     |            | Low                                                         | -             | -       | -             | -       |
| x2 mode<br>CCxP = 1 | 1100       | High                                                        | -             | -       | -             | -       |
|                     |            | Low                                                         | Minus         | Minus   | Add           | Add     |
| x1 mode<br>CCxP = 0 | 1101       | High                                                        | -             | Minus   | -             | Add     |
|                     |            | Low                                                         | -             | -       | -             | -       |
| x1 mode<br>CCxP = 1 | 1101       | High                                                        | -             | -       | -             | -       |
|                     |            | Low                                                         | Minus         | -       | Add           | -       |

#### 20.2.17.4 Index input

The counter may be reset by an index signal output by the encoder for indicating an absolute reference position. The index signal must be connected to the tim\_etr input. It may be filtered by a digital filter.

The IE bit of the TIMx\_ECR register enables the index function, and the IE bit can only be enabled in encoder mode, that is, when the SMS [3: 0] is configured to the following values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111

As shown in the figure below, commercial encoders have several options for index pulse adjustment

- Gating of A and B: The pulse width is 1/4 of a channel, aligned with the edges of A and B
- Gating of A (gating of B): The pulse width is 1/2 of a channel, aligned with the edge of A
- Ungated: Pulse width up to one channel period, not aligned with channel edge

Figure 20-52 Index gating selection

The figure below shows that the circuit can tolerate the jitter of the index signal in any gating mode. In ungated mode, the index signal pulse width needs to be strictly less than 2 encoder cycles. If greater than or equal to 2 cycles, the counter will be reset multiple times.

Figure 20-53 Index signals for jitter

The timer fully supports 3 gating modes and does not require special programming. It only needs to define what state of the encoder (the combination of channel A and channel B states) the index signal needs to be synchronized. By configuring the IPOS [1: 0] of the TIMx\_ECR register.

The detection event of the index signal varies depending on the counting direction to ensure symmetrical operation during the rotation direction flip.

- The counter is reset during up count (DIR = 0)
- When counting down, the counter value is set to TIMx\_ARR

This allows indexes to be generated at the same mechanical angular position regardless of the counting direction. The figure below shows which position indexes are generated, for a simple example (one encoder provides 4 mechanical rotations along each standard)

Figure 20-54 Index Generation at IPOS [1: 0] = 11

The following figure shows the waveform and corresponding values at IPOS [1: 0] = 11, which indicates that the moment when the counter value is forced is automatically adjusted according to the counting direction

- Counter cleared When the encoder enters 11 state (channel A = 1, channel B = 1), counting up (DIR = 0)
- The counter value is set to TIMx\_ARR when leaving the 11 state, counting down (DIR = 1)

Index detection events can generate interrupts

The arrow indicates which conversion process index event interrupt is generated

Figure 20-55 Index at IPOS [1: 0] = 11 and count values at channel A gated mode

The following figure shows the waveform and corresponding values in ungated mode, with arrows indicating which transition the index event interrupt occurred

Figure 20-56 Count values in ungated index mode at IPOS [1: 0] = 00

The following figure shows the waveforms and corresponding values in A and B gated modes, with arrows indicating which transition process index event interrupt occurs

Figure 20-57 indexes and count values when channels A and B are gated

The following two figures illustrate in detail cases where the index pulse width is less than 1/4 of the encoder period

Figure 20-58 Operation of encoder mode with narrow index pulse at IPOS [1: 0] = 11

Figure 20-59 ARR = 0x07 time-to-time narrow index pulse reset counter

The following figure shows in detail how indexes are managed in x1 and x2 schemas

Figure 20-60 IPOS [1: 0] = 01 in x1 and x2 modes

■ Directional index sensitivity

You can allow the index to be valid only in the selected counting direction by configuring the IDIR [1: 0] of the TIMx\_ECR register.

The following figure shows the relationship between values, indexes, and count reset events based on IDIR [1: 0].

Note: IDIR must be written until the IE bit is reset (index mode is off)

Note: Directional index sensitivity does not support clock + directional mode, when SMS = 1010 or 1011, IDIR must be set to 00

Figure 20-61 oriented index sensitivity

#### ■ Special First Index Event Management

The FIDX bit of the TIMx\_ECR register allows indexing to be performed only once, as shown in the figure below. When the first index arrives, the subsequent indexes are ignored. If desired, the circuit can be re-enabled by writing the FIDX bit to 0 and then to 1.

Note: When FIDX = 1, if the direction changes at position 0 (index active), index may be issued twice (IDXF flag set)

Figure 20-62 Counter reset when FIDX bit is set

#### ■ Index management in non-orthogonal mode

The following two figures describe in detail how indexes are managed in directional clock mode and clock + directional mode. I.e. SMS = 1010 or 1011

In these modes, the sensitivity of the index is determined by the IPOS

IPOS [0] = 0: Detect index at low level of clock

IPOS [0] = 1: Detect index at high level of clock

IPOS [1] has no effect.

Figure 20-63 clock plus directional mode index behavior (IPOS [0] = 1)

Figure 20-64 oriented clock mode index behavior (IPOS [0] = 1)

#### Encoder Error Management

There are 2 quadrature signals in the encoder configuration that are valid, and it is necessary to detect conversion errors. The readings on the 2 inputs correspond to 2-digit Gray codes to represent the state diagram, as shown in the figure. You can only change 1 bit at a time. The erroneous transition pulls up the interrupt flag TERRF in the TIMx\_SR status register. If the TERRIE position of the TIMx\_DIER register is 1, a transition error interrupt will be generated.

Figure 20-65 Schematic diagram of orthogonal coded signal states

After the encoder has the index signal, it can detect abnormal operation that causes pulse excess during each rotation. The encoder will provide N pulses per rotation and will produce a  $4 * N$  count. The index signal resets the counter every  $4 * N$  clock cycles.

If the counter value is tapered from TIMx\_ARR to 0 or from 0 to TIMx\_ARR without an index event, this is reported as an index position error.

The overflow threshold is configured by the TIMx\_ARR register. The resulting count value of the 1000-line encoder ranges from 0 to 3999 (in 4x read mode). The overflow detection threshold must be set to  $TIMx\_ARR = 3999 + 1 = 4000$

When counting up, the error is asserted when the transition is delayed to 0 to 1. The figure below shows the processing of narrow index signals in A and B gated modes.

Figure 20-66 Error detection when is coded up

When counting down, the detection must be based on the previous transition from 1 to 0. The figure below shows the processing of narrow index signals in A and B gated modes. In order to avoid the encoder immediately after index detection jitter between the two values of TIMx\_ARR and 0, and erroneously generate false determination.

Figure 20-67 Error Detection when Downcoding

An index error will pull up the IERRF interrupt flag bit of the TIMx\_SR status register. If the TERRIE position of the TIMx\_DIER register is 1, a transition error interrupt will be generated.

#### ■ Functional encoder interrupt

The following interrupt are all valid in encoder mode

- **Direction change:** In encoder mode, any change in counting direction will cause the DIR bit of TIMx\_CR1 to flip, and the change in direction will pull up the DIRF interrupt flag bit of the TIMx\_SR status register. If the DIRIE bit of the TIMx\_DIER register is enabled, a change of direction interrupt is also generated
- **Index event:** The index event will pull up the IDXF interrupt flag bit of the TIMx\_SR status register. An index interrupt is also generated if the IDXIE bit of the TIMx\_DIER register is enabled
- **Runtime updates encoder mode from mode preload function**

It is necessary to switch from one encoder mode to another operation mode, which is usually done at high speeds to reduce the rate of update interrupts. The figure below shows switching from x4 mode to x2 mode and then switching to x1 mode.

For this purpose, SMS [3: 0] can be preloaded. The enable bit is controlled by the SMSPE bit of the TIMx\_SMCR register. The selection of the trigger signal from the SMS [3: 0] preload to the active value can be controlled using the SMSPS bit of the TIMx\_SMCR register.

- **SMSPS = 0:** Transmission is triggered by UEV, this mode must turn off the index function (IE = 0)
- **SMSPS = 1:** Transfer triggered by index event

Figure 20-68 The encoder mode is updated by preload when event updates

#### Encoder clock output

The working principle of the encoder is not entirely suitable for high-resolution fast measurements. At low speeds, it requires a considerable integration time to have a sufficient number of clock edges and accurate measurements.

At low speeds, the best way is to measure the edge-to-edge clock cycle directly. You may need to use a slave timer at this time. The timer may output the clock signal of the encoder through `tim_trgo`. The slave timer may perform cycle measurements and provide speed information for each encoder clock edge.

This mode is enabled by setting `MMS [3: 0] = 1000` of the `TIMx_CR2` register. And can only be used if the `SMS [3: 0]` is configured to 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Other `SMS [3: 0]` values are not allowed and may produce unexpected behavior.

#### 20.2.18 Directional bit output

It is also necessary to output the direction bit of the timer, which is output from the OC3 and OC4 channels by configuring the `OC3M [3: 0]` and `OC4M [3: 0]` bit segments of the `TIMx_CCMR2` register to 1011 (copying the `DIR` bit of the `TIMx_CR1` register).

This feature is used to monitor the counting direction (or rotation direction) of the encoder, or can provide an indication signal of the upper/lower stages in the intermediate alignment PWM mode.

#### 20.2.19 UIF bit remapping

The `UIFREMAP` bit of the `TIMx_CR1` register can force a continuous copy of the UIF to the 31st bit of the timer counter (`TIMxCNT [31]`). This allows both the value of the counter and a potential rolling state exhibited by the `UIFCPY` flag signal to be read out. In special cases, this can simplify the calculation by avoiding race conditions, for example by simultaneous processing of counter readout and update interrupts.

The UIF and `UIFCPY` flags are generated without delay.

In a 32-bit timer implementation, when the `UIFREMAP` bit is set, 31 bits of the counter are overwritten by the `UIFCPY` flag on read access (the most significant bit of the counter is only accessible in write mode).

### 20.2.20 Timer input XOR function

The TI1S bit in the TIMx\_CR2 register allows the input filter of channel 1 to be connected to the output of an exclusive OR gate, whose three inputs are TIMx\_CH1, TIMx\_CH2 and TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

### 20.2.21 Synchronization of TIMx timer and externally triggered

The TIMx timer can be synchronized with an external trigger in multiple modes: reset mode, gated mode, trigger, reset + trigger and gated + reset mode.

#### 20.2.21.1 Slave mode: Reset mode

When a trigger input event occurs, the counter and its prescaler can be re-initialized; Meanwhile, if the UDIS bit of the TIMx\_CR1 register is low, an update event UEV is also generated; All preload registers (TIMx\_ARR, TIMx\_CCRx) are then updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=0100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. At the same time, a trigger flag (TIF bit in the TIMx\_SR register) is set, and an interrupt request or a DMA request is generated according to the setting of the TIE (Interrupt Enable) bit and the TDE (DMA Enable) bit in the TIMx\_DIER register.

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 20-69 Control circuit in reset mode

#### 20.2.21.2 Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this

example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).

- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register. In gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level.

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 20-70 Control circuit in Gated mode

### 20.2.21.3 Slave mode: Trigger mode

The selected event on the input enables the counter.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Figure 20-71 Control circuit in trigger mode

#### 20.2.21.4 Slave mode: reset plus trigger combination mode

In this mode, the rising edge of the trigger input initializes the counter and generates an update signal for the register, turning on the counting

This mode is used for a single pulse mode

#### 20.2.21.5 Slave mode: gating plus reset combination mode

The clock of the counter is enabled only when the trigger input is high. The counter stops when the trigger signal is pulled low. The start and stop of the counter can be controlled

This mode allows detection of out-of-range PWM signals (duty cycle exceeding maximum expected value)

#### 20.2.21.6 Slave mode: External clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit through the TIMx\_SMCR register:

— ETF = 0000: no filter

— ETPS = 00: prescaler disabled

— ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Channel 1 is configured as follows to detect the rising edge of TI1:

— IC1F = 0000: no filter

— The capture prescaler is not used for triggering, so it does not need to be configured.

— CC1S=01 in TIMx\_CCMR1 register to select only the input capture source

— Set CC1P = 0 in the TIMx\_CCER register to determine polarity (only rising edges are detected)

3. Set SMS = 110 in the TIMx\_SMCR register, and configure the timer to trigger mode. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

Figure 20-72 Control Circuit in External Clock Mode 2 + Trigger Mode

### 20.2.22 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master mode, it can reset, start, stop or clock the counter of another Timer configured in Slave mode.

The following presents an overview of the trigger selection and the master mode selection blocks.

#### 20.2.22.1 Using one timer as prescaler for another timer

Figure 20-73 Master/Slave timer example

Figure 20-74 Example of master-slave connection with only 1 channel timer

A timer with only one channel (see image above) does not have a master mode. However, the tim\_oc1 output signal may be used as a flip-flop for the slave timer. The tim\_oc1 signal pulse width must be programmed to at least 2 clock cycles of the target timer to ensure that the slave timer detects a trigger. For example, if the target timer clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

For example, TIM\_mstr can be configured as the prescaler of TIM\_slv. Referring to FIGS. 20-73, the following is performed:

- TIM\_mstr is configured as the main mode, which can output a periodic trigger signal every time the event UEV is updated. When MMS = '010' of the TIM\_mstr\_CR2 register, a rising edge signal is output on TRGO1 every time an update event occurs.
- The TRGO1 output of TIM\_mstr is connected to TIM\_slv, TS = '00000' of the TIM\_slv\_SMCR register is set, and TIM\_slv is configured to be a slave mode using ITR1 as an internal trigger.
- The slave mode controller is then placed in external clock mode 1 (SMS = 111 for the TIM\_slv\_SMCR register); In this way, TIM\_slv can be driven by the periodic rising edge of TIM\_mstr (i.e., counter overflow of TIM\_mstr) signal.
- Finally, the respective CEN bits must be set to start two timers respectively.

Note: If OCx has been selected as the trigger output of TIM\_mstr (MMS = 1xx), its rise is used to drive the counter of TIM\_slv.

#### 20.2.22.2 Using one timer to enable another timer

In this example, the enablement of TIM\_slv is controlled by the output comparison of TIM\_mstr. TIM\_slv counts the divided internal clock only when the OC1REF of TIM\_mstr is high. The clock frequencies of both timers are obtained by dividing CK\_INT by 3 by the prescaler ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure TIM\_mstr as the main mode, and send its output comparison reference signal (OC1REF) as the trigger output (MMS of TIM\_mstr\_CR2 register = 100)
- OC1REF waveform configuring TIM\_mstr (TIM\_mstr\_CCMR1 register)
- Configure TIM\_slv to get input trigger from TIM\_mstr (TS = 00000 for TIM\_slv\_SMCR register)
- Configure TIM\_slv in gated mode (SMS = 101 for TIM\_slv\_SMCR register)
- Set CEN = 1 of the TIM\_slv\_CR1 register to enable TIM\_slv
- Set CEN = 1 of TIM\_mstr\_CR1 register to start TIM\_mstr

Note: The clock of TIM\_slv is not synchronized with the clock of TIM\_mstr. This mode only affects the enable signal of the TIM\_slv counter.

Figure 20-75 OC1REF Control TIM\_slv for TIM\_mstr

In the example above, their counters and prescalers are not initialized before TIM\_slv starts, so they start counting from the current value. You can reset the two timers before starting TIM\_mstr, so that they start with a given value, that is, write any value desired in the timer counter. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example, TIM\_mstr and TIM\_slv need to be synchronized. TIM\_mstr is the master mode and starts from 0, TIM\_slv is the slave mode and starts from 0xE7; The prescaler coefficients of the two timers are the same. Writing '0' to the CEN bit of TIM\_mstr\_CR1 disables TIM\_mstr, and TIM\_slv stops.

- TIM\_mstr is configured as the main mode, and the output comparison 1 reference signal (OC1REF) is sent as the trigger output (MMS of the TIM\_mstr\_CR2 register = 100).
- The OC1REF waveform of TIM\_mstr is configured (TIM\_mstr\_CCMR1 register).
- Configure TIM\_slv to get input trigger from TIM\_mstr (TS = 00000 for TIM\_slv\_SMCR register)
- Configure TIM\_slv in gated mode (SMS = 101 for TIM\_slv\_SMCR register)
- Set UG = '1' of the TIM\_mstr\_EGR register to reset TIM\_mstr.
- Set UG = '1' of the TIM\_slv\_EGR register to reset TIM\_slv.
- Write '0xE7' to the counter of TIM\_slv (TIM\_slv\_CNT), initializing it to 0xE7.
- Set CEN = '1' of the TIM\_slv\_CR1 register to enable TIM\_slv.
- Set CEN = '1' of the TIM\_mstr\_CR1 register to start TIM\_mstr.
- Set CEN = '0' of the TIM\_mstr\_CR1 register to stop TIM\_mstr.

Figure 20-76 TIM\_slv can be controlled by enabling TIM\_mstr

### 20.2.22.3 Using one timer to start another timer

In this example, TIM\_slv is enabled using the update event of TIM\_mstr. Once TIM\_mstr generates an update event, TIM\_slv starts counting from its current value (which may be non-0) according to the divided internal clock. Upon receipt of the trigger signal, the CEN bit of TIM\_slv is automatically set to '1' and the counter starts counting until '0' is written to the CEN bit of the TIM\_slv\_CR1 register. The clock frequency of both timers is divided by 3 by the prescaler pair of CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure TIM\_mstr as the main mode and send its update event (UEV) as the trigger output (MMS = 010 of the TIM\_mstr\_CR2 register).
- Configure the cycle of TIM\_mstr (TIM\_mstr\_ARR register).
- Configure TIM\_slv to get input trigger from TIM\_mstr (TS = 00000 for TIM\_slv\_SMCR register)
- Configure TIM\_slv to trigger mode (SMS of TIM\_slv\_SMCR register = 110)

- Set CEN = 1 of the TIM\_mstr\_CR1 register to start TIM\_mstr.

Figure 20-77 triggers TIM\_slv using the update of TIM\_mstr

As in the previous example, the user can initialize both counters before starting counting. The following figure shows the action of using the trigger mode instead of the gated mode (SMS = 110 of the TIM\_slv\_SMCR register) with the same configuration as 0.

Figure 20-78 triggers TIM\_slv with the enable of TIM\_mstr

#### 20.2.22.4 Starting 2 timers synchronously in response to an external trigger

This example enables TIM\_mstr when the TI1 input of TIM\_mstr rises, and enables TIM\_slv while enabling TIM\_mstr. To ensure the alignment of counters, TIM\_mstr must be configured in master/slave mode (corresponding to TI1 as slave, corresponding to TIM\_slv as master):

- Configure TIM\_mstr as the main mode and send its enable as the trigger output (MMS = 001 of the TIM\_mstr\_CR2 register).
- Configure TIM\_mstr in slave mode and obtain input trigger from TI1 (TS = 00100 of the TIM\_mstr\_SMCR register).
- Configure TIM\_mstr to trigger mode (SMS = 110 of TIM\_mstr\_SMCR register).
- Configure TIM\_mstr in master/slave mode with MSM = 1 of the TIM\_mstr\_SMCR register.
- Configure TIM\_slv to get input trigger from TIM\_mstr (TS = 00000 of the TIM\_slv\_SMCR register).

- Configure TIM\_slv to trigger mode (SMS = 110 of TIM\_slv\_SMCR register).

When a rising edge appears on TI1 of TIM\_mstr, the two timers start counting according to the internal clock synchronously, and the two TIF flags are also set at the same time.

Note: In this example, both timers are initialized (set the corresponding UG bits) before starting, and both counters start at 0, but an offset can be inserted between timers by writing to either counter register (TIMx\_CNT). In the figure below, you can see that there is a delay between CNT\_EN and CK\_PSC of TIM\_mstr in master/slave mode.

Figure 20-79 Triggers TIM\_mstr and TIM\_slv using the TI1 input of TIM\_mstr

### 20.2.23 DMA Burst Mode

The TIMx timer has the ability to generate multiple DMA requests when a single event occurs. The main purpose is to be able to reprogram some functions of the timer multiple times without the overhead of software. But it is also possible to read several registers in a row at fixed intervals.

The destination of the DMA controller is unique and must point to the virtual register TIMx\_DMAR. When a given timer event occurs, the timer initiates a series of DMA requests. Each write to the TIMx\_DMAR register actually redirects a timer register.

The DBL [4: 0] bit in the TIMx\_DCR register sets the DMA burst length. When a read or write access is made to a TIMx\_DMR address, the timer recognizes burst transmissions, that is, the number of transmissions (in half a word or byte)

The DBA [4: 0] bit of TIMx\_DCR defines the DMA base address for DMA transmission (when read and write operations are completed through the TIMx\_DMAR address). The DBA is defined as the offset from the TIMx\_CR1 register address.

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst characteristic is used to update the contents in the CCRx register when an update event occurs, transmitting a half-word to CCRx by DMA.

This is done through the following steps:

1. Configure the corresponding DMA channel as follows:
  - 1) The DMA channel peripheral address is the address of the DMAR register
  - 2) The DMA channel storage address is the BUFF address in RAM, which contains the data transmitted by DMA to CCRx
  - 3) Number of data transmitted = 3
  - 4) Polling Mode Off
2. Configure DCR registers by configuring DBA and DBL: DBL = 3, DBA = 0XE
3. Enable timer update DMA request (UDE = 1)
4. Enable timer
5. Enable the DMA channel

This example applies to the case where each CCRx register is updated once. If each CCRx is updated twice, the number of data transfers needs to be set to 6. For example, assume that the buffer of RAM contains data1, data2, data3, data4, data5 and data6. Data is sequentially transmitted to CCRx: the first update DMA request, data1 is transmitted to CCR2, data2 is transmitted to CCR3, and data3 is transmitted to CCR4; For the second update DMA request, data4 is transmitted to CCR2, data5 is transmitted to CCR3, and data6 is transmitted to CCR4.

Note: Null values can be written to the reserved register

#### 20.2.24TIM2/3/4/5/18 DMA Request

TIM2/3/4/5/18 can generate DMA requests as shown in the following table:

Table 20-4 DMA Request

| DMA request source   | DMA enable control bit |
|----------------------|------------------------|
| update               | UDE                    |
| Compare/Capture 1    | CC1DE                  |
| Compare/Capture 2    | CC2DE                  |
| Comparison/Capture 3 | CC3DE                  |
| Comparison/Capture 4 | CC4DE                  |
| Trigger              | TDE                    |

#### 20.2.25Debug mode

When the microcontroller enters debug mode (Cortex-M4F core stops), according to the setting of DBG\_TIMx\_STOP in the DBG module,

The TIMx counter may either continue normal operation or stop. See subsequent DBG sections for details.

Behavior in debug mode can be programmed using a dedicated configuration for each timer in the Debug Support Module (DBG)

For safety reasons, when the counter stops, the output is disabled (if the MOE is reset). The output can be forced to an invalid level (OSS1 = 1), or taken over by the GPIO controller (OSS1 = 0), typically forced to high impedance.

For more details, see the DBG module description

### 20.2.26 TIM2/3/4/5/18 low power mode

| Mode    | Description                                                                              |
|---------|------------------------------------------------------------------------------------------|
| Sleep   | No effect, peripheral is active. Interruption may cause device to exit sleep             |
| Stop    | The timer operation stops and the register contents remain. Cannot generate an interrupt |
| Standby | The timer has been powered down and must be reinitialized after exiting standby mode.    |

### 20.2.27 TIM2/3/4/5/18 Interrupted

| Interrupt event            | Event flag | Interrupt enable control bit |

| 6: 4  | MMS      | RW | 3'h0 | Main mode selection (Master mode selection)<br>For selecting synchronization information (TRGO) to be sent to the slave timer in master mode. The combination is as follows:<br>0000: Reset-The UG bit of the TIMx_EGR register is used as a trigger output (TRGO). If the reset is generated by the trigger input (the slave mode controller is in reset mode), the signal on the TRGO will have a delay relative to the actual reset.<br>0001: Enable-Counter enable signal CNT_EN may be used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the counter enable signal is controlled by the trigger input, there is a delay on the TRGO unless the master/slave mode is selected (see description of the MSM bit in the TIMx_SMCR register).<br>0010: Update-The update event is selected as Trigger Output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.<br>0011: Comparison Pulse-When a catch occurs or a comparison is successful, when the CC1IF flag is to be set (even if it is already high), the trigger output sends a positive pulse (TRGO).<br>0100: Compare - OC1REFC signal is used as trigger output (TRGO)<br>0101: Compare - OC2REFC signal is used as trigger output (TRGO)<br>0110: Compare - OC3REFC signal is used as trigger output (TRGO)<br>0111: Compare - OC4REFC signal is used as trigger output (TRGO)<br>1000: Encoder clock output-encoder clock signal as trigger output (TRGO). This encoded value is only valid if the SMS [3: 0] has values of 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Other SMS values may result in unexpected effects.<br>1001-1111: Reserved<br>Note:<br>1. The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed.<br>2. If the master and slave timers are not on the same bus, the master mode should be configured to the width that can be picked by the slave timer. |

The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:<br>0000: No filter, sampling is done at fDTS<br>0001: fSAMPLING = fCK_INT, N = 2<br>0010: fSAMPLING = fCK_INT, N = 4<br>0011: fSAMPLING = fCK_INT, N = 8<br>0100: fSAMPLING = fDTS/2, N = 6<br>0101: fSAMPLING = fDTS/2, N = 8<br>0110: fSAMPLING = fDTS/4, N = 6<br>0111: fSAMPLING = fDTS/4, N = 8<br>1000: fSAMPLING = fDTS/8, N = 6<br>1001: Sampling frequency fSAMPLING = fDTS/8, N = 8<br>1010: Sampling frequency fSAMPLING = fDTS/16, N = 5<br>1011: fSAMPLING = fDTS/16, N = 6<br>1100: fSAMPLING = fDTS/16, N = 8<br>1101: fSAMPLING = fDTS/32, N = 5<br>1110: fSAMPLING = fDTS/32, N = 6<br>1111: fSAMPLING = fDTS/32, N = 8 |
| 7      | MSM       | RW | 0    | Master/slave mode<br>0: No action;<br>1: The event on the trigger input (TRGI) is delayed to allow perfect synchronization between the current timer (via TRGO) and its slave timers. It is useful if we want to synchronize several timers on a single external event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 2: 0 | SMS  | RW | 3'h0 | <p>Select from Mode (Slave mode selection)<br/> When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).<br/> 0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.<br/> 0001: Quadrature Encoder Mode 1, x2 Mode-The counter counts up/down on the edge of TI1FP1 depending on the level of TI2FP2.<br/> 0010: Quadrature Encoder Mode 2, x2 Mode-The counter counts up/down on the edge of TI2FP2 depending on the level of TI1FP1.<br/> 0011: Quadrature Encoder Mode 3, x4 Mode-The counter counts up/down on the edges of TI1FP1 and TI2FP2 depending on the input level of the other signal.<br/> 0100: Reset Mode-The rising edge of the selected trigger input (TRGI) re-initializes the counter and generates a signal to update the register.<br/> 0101: Gated mode-When the trigger input (TRGI) is high, the clock of the counter is turned on. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.<br/> 0110: Trigger mode-The counter starts (but does not reset) on the rising edge of the trigger input TRGI, only the start of the counter is controlled.<br/> 0111: External clock mode 1-The rising edge of the selected trigger input (TRGI) drives the counter.<br/> 1000: Reset + Trigger Combination Mode:-Rising edge of Trigger Input (TRGI) initializes counter, generates register update and starts counter<br/> 1001: Gate + Reset Combination Mode:-Trigger input (TRGI) is high when counter clock enabled. The counter stops and resets once the trigger signal is pulled low. The start and stop of the counter are controllable.<br/> 1010: Encoder mode: clock + direction, x2 mode<br/> 1011: Encoder mode: clock + direction, x1 mode, sensitivity of TI2FP2 set by CC2P<br/> 1100: encoder mode: directional clock, x2 mode<br/> 1101: Encoder mode: directional clock, x1 mode, sensitivity of TI1FP1, TI2FP2 set by CC1P and CC2P<br/> 1110: quadrature encoder mode: x1 mode. Count only at the edge of TI1FP1, the edge sensitivity is set by CC1P<br/> 1111: quadrature encoder mode: x1 mode. Counted only at the edge of TI2FP2, the edge sensitivity is set by CC2P<br/> Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.<br/> Note: Do not use UEV as the tim_trgo output signal in encoder mode(i.e. mms cannot be configured to 010).</p> |

| 6: 4      | OC1M     | RW  | 3'h0        | Output Comparison 1 Mode Output Compare 1 mode<br>These bits define the action of outputting the reference signal OC1REF, and OC1REF determines the values of OC1, OC1N. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.<br>0000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.<br>0001: Set channel 1 to active level on match. When the value of counter TIMx_CNT is the same as that of capture/compare register 1 (TIMx_CCR1), OC1REF is forced to be high.                                                 |
